CS5219 2007-08 by Abhik 1

# MC

- Model checking is a search based procedure applicable to only finite state systems.
- Extension to infinite state systems (arising out of infinite data domains) handled by abstraction of memory store.
- Requires human ingenuity in choice of the abstract predicates.

CS5219 2007-08 by Abhik 2

# Abstraction Refinement

- Given a program P and a property f, very difficult to get the "right" abstraction which will be able to prove f (even if f is true).
- Instead start with a very coarse abstraction and model check the resultant abstract model.
- Counter-example generated may not correspond to any concrete trace of P.
  - Refine the abstract model.

CS5219 2007-08 by Abhik 3

# Software Model Checking without Refinement

CS5219 2007-08 by Abhik 4

# ... and with Refinement

CS5219 2007-08 by Abhik 5

# Impossible paths

$v = 0;$   
 if ( $v < 0$ ) then S1  
 if ( $u < 0$ ) then S1  
 if ( $u > 0$ ) then S2.

$v = 0$   
 S1  
 S1  
 S2

CS5219 2007-08 by Abhik 6

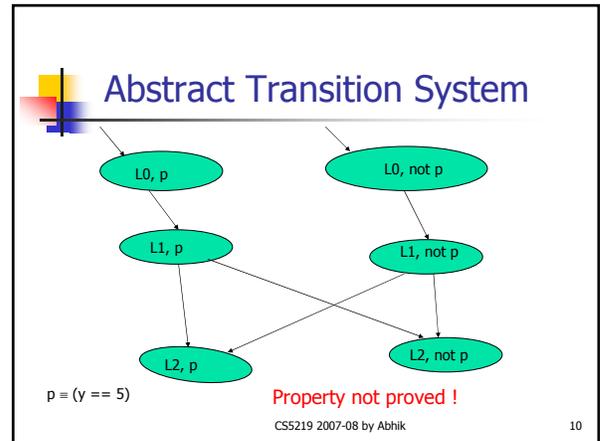

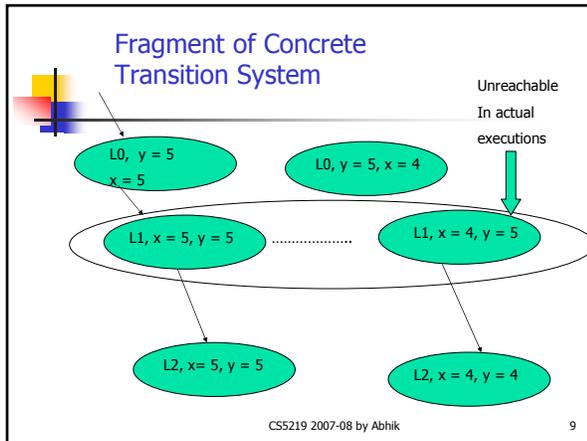

for (j=1 to 100) do  
 if j%2 == 0 then  
   S1...  
 else S2  
 endfor

CS5219 2007-08 by Abhik 7

### An example program

- L0:  $x = 5$
- L1:  $y = x$
- L2
- Property  $G (pc = L2 \Rightarrow y = 5)$
- Suppose we abstract with  $(y = 5)$

CS5219 2007-08 by Abhik 8

### Abstract counter-example

- The following can be a counter-example trace returned by model checking
  - $\langle L0, p \rangle, \langle L1, p \rangle, \langle L2, not\ p \rangle$
- But this does not correspond to any execution of the concrete program.
- This is a spurious counter-example
- Need to input new predicates for abstraction.

CS5219 2007-08 by Abhik 11

### Abstraction refinement

- Generate the new predicates by analyzing the counter-example trace.
- A more informative view of the program's memory store is thus obtained.
- But how to establish a correspondence between the abstract counter-example and the concrete program ?

CS5219 2007-08 by Abhik 12

## An Example

- Initially  $x == 0$
- L0: while (1) {
- L1: x++;
- L2: while (x > 0) x - - ;
- L3 }

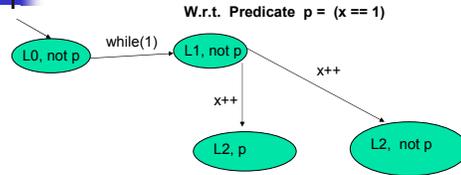

Property:  $AG(pc == L2 \Rightarrow x == 1)$

A locational invariant

CS5219 2007-08 by Abhik

13

## Initial Abstraction

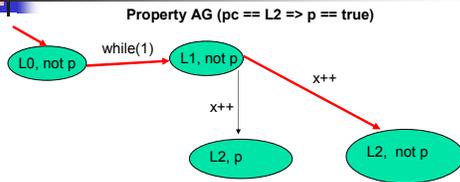

No need to traverse further, counter-example trace found.

CS5219 2007-08 by Abhik

14

## Counter-example

The predicate  $p$  denotes  $(x == 1)$

CS5219 2007-08 by Abhik

15

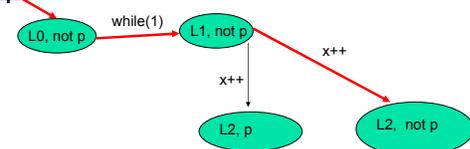

## Counter-example verification

- The counter-example may be **spurious** because our abstraction was too coarse.
  - The sequence of statements in the control-flow graph constitute an infeasible path in Control Flow Graph.
  - Not part of any concrete execution trace in the program.
- How to check whether the produced counter-example trace is spurious?
  - Backwards or forwards exact reasoning on the counter-example trace.
  - Backwards reasoning shown now, forwards reasoning later in the lecture.

CS5219 2007-08 by Abhik

16

## Exact reasoning

$(L2, x \neq 1) \leftarrow (L1, x \neq 0) \leftarrow (L0, x \neq 0) \leftarrow \text{Initially } (x \neq 0 \wedge x = 0)$   
 -- the constraint to hold initially is unsatisfiable.

CS5219 2007-08 by Abhik

17

## One step of exact reasoning

What is the weakest constraint on data states that should hold at L1, such that when control moves to L2 (by executing  $x++$ ), the data state at L2 is guaranteed to satisfy  $x \neq 1$ ?

- Weakest pre-condition (WP) computation.
- We repeat the WP computation until we reach the end of the trace OR the constraint accumulated becomes unsatisfiable.
- Corresponds to Real counter-example OR spurious counter-example.

CS5219 2007-08 by Abhik

18

Effect constraint of each statement  
 $\Psi(x, x')$   
 e.g. effect constraint of  
 $x++$  is  
 $x' = x + 1$

CS5219 2007-08 by Abhik 19

$wp(x)$   
 $= \forall x' \Psi(x, x') \Rightarrow c(x')$   
 $x' = x + 1 \Rightarrow x' > 4$   
 $(x > 3)$

CS5219 2007-08 by Abhik 20

So, what do we know ?

- We are verifying an invariant  $\varphi$  against an infinite state system M.
- We abstracted (the data states of) M w.r.t.  $p_1, \dots, p_k$  to get M1
  - For every trace  $c_1, c_2, \dots, c_n$  (statement sequences) in M, there is a trace  $c_1, c_2, \dots, c_n$  in M1 (not vice-versa)
- Model check  $M1 \models \varphi$  to
  - Case 1: Success. We have proved  $M \models \varphi$
  - Case 2: We get a counter-example trace  $\sigma_1$ 
    - Need to check whether  $\sigma_1$  is "spurious"

CS5219 2007-08 by Abhik 21

What is "spurious" ?

- Each trace in M (concrete system) has a corresponding trace with same statement sequence in M1 (abstract system).
- A trace in M1 may not have a corresponding trace with same statement sequence in M.
- Does the counter-example trace  $\sigma_1$  in M1 have a corresponding trace  $\sigma$  with same statement sequence in M ?
  - If not, then  $\sigma_1$  is a spurious counter-example

CS5219 2007-08 by Abhik 22

What if spurious ?

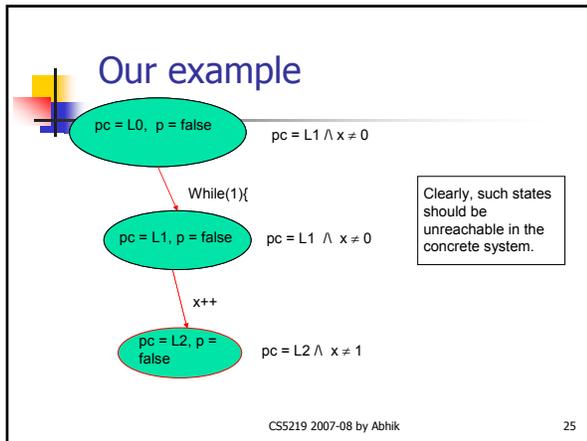

- So, we discussed how to check whether an obtained counter-example is spurious.
- If  $\sigma_1$  is not spurious, then we have proved that M (concrete sys.) does not satisfy  $\varphi$
- If  $\sigma_1$  is spurious, we need to refine the abstraction of M
  - Original abs: Predicates  $p_1, \dots, p_k$
  - New abs: Preds  $p_1, \dots, p_k, p_{(k+1)}, \dots, p_n$

CS5219 2007-08 by Abhik 23

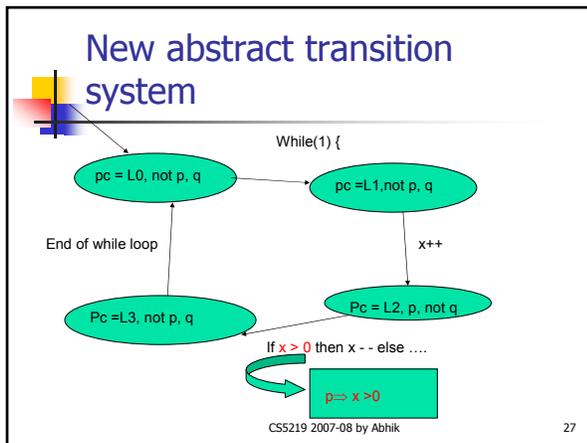

But how do we ...

- ... compute the new preds  $p_{(k+1)}, \dots, p_n$  ?
  - No satisfactory answer, active topic of research in the verification community.
  - All existing approaches are based on analysis of the spurious counter-example trace  $\sigma_1$
  - Concretize the abstract states of  $\sigma_1$  to get constraints on concrete data states.
  - But several ways to glean the new predicates from these constraints.
    - We will just look at some possible heuristics.

CS5219 2007-08 by Abhik 24

- ### New predicates
- Based on the spurious trace, we choose another predicate  $q = (x = 0)$ 
    - No clear answer why, different research papers give different heuristic 'justifications'.
  - Again abstract the concrete program w.r.t. the predicates
    - $p = (x = 1)$
    - $q = (x = 0)$
- CS5219 2007-08 by Abhik 26

- ### Final result
- Model checking the new abstract transition system w.r.t.
    - $AG( pc == L2 \Rightarrow x == 1 )$
  - ... yields no counter-example trace.
  - Constitutes a proof of
  - $M \models AG( pc == L2 \Rightarrow x == 1 )$
  - Where M is the transition system corresponding to original program.
- CS5219 2007-08 by Abhik 28

- ### Constructing Explanations
- Start from the end (or beginning of the trace)
    - Strongest post condition (SP), [ next slide ]
    - Or Weakest Pre condition (WP) [discussed]
  - Perform exact reasoning at each step until you hit unsatisfiability
  - Greedily remove one constraint at a time from the unsatisfiable constraint store until it becomes satisfiable
    - Is that sufficient ?
- CS5219 2007-08 by Abhik 29

- ### SP along a trace
- assume( $b > 0$ )     $b > 0$
  - $c := 2*b$      $b > 0, c = 2b$
  - $a := b$      $b > 0, c = 2b, a = b$
  - $a := a - 1$      $b > 0, c = 2b, a = b-1$
  - assume ( $a < b$ )     $b > 0, c = 2b, a = b-1, a < b$
  - assume ( $a = c$ )     $b > 0, c = 2b, a = b-1, a < b, a = c$
  - Conjunction shown with comma.
- CS5219 2007-08 by Abhik 30

## Choosing predicates

- $b > 0, c = 2b, a = b - 1, a < b, a = c$
- Removing  $a = b - 1$  makes the constraint satisfiable
  - Should we choose it?
- Is it sufficient to choose predicates from the formula which is unsatisfiable?
- **Exercise:** Try to work out the backwards traversal and investigate choices of predicates.

CS5219 2007-08 by Abhik

31

## Choosing predicates

- $a := b;$                      $a = b$
- $a := a - 1;$                  $a = b - 1$
- $\text{assume}(a \geq b)$             $a = b - 1, a \geq b$
- If we choose  $a = b - 1, a \geq b$  as new refinement it may not suffice.
- The effect of  $a := b$  can only be accurately captured by the pred  $(a = b)$
- So, we need all predicates whose **transformation** leads to one of the predicates causing unsatisfiability.

CS5219 2007-08 by Abhik

32

## Exercise

- Try verifying absence of error in
  - $a := b; a := a - 1; \text{if } (a \geq b) \{ \text{error} \}$
- Using the predicates
  - $\{a \geq b\}$
  - $\{a \geq b, a = b - 1\}$
- Feel free to use forwards or backwards counter-example analysis ...

CS5219 2007-08 by Abhik

33

## Additional: Dealing with pointers

- ```
int *p, *q;
void main(){
  if (*p == 3){
    *q = 2;
    if (*p == 2){
      *p = 3;
      if (*q == 2){
        ERROR
      }
    }
  }
}
```
- $p$  may or may not be **aliased** to  $q$
- **Is the ERROR state ever reachable?**

CS5219 2007-08 by Abhik

34

## Use pointer analysis

- Can  $p$  ever alias to  $q$ 
  - Static analysis, flow insensitive.
- If yes, then need to consider both the aliased and non-aliased cases
  - Corresponding to truth of  $p=q$  which is also maintained as a predicate.
  - Infeasible constraint store has disjunction
    - $(p = q \wedge \dots \wedge \dots) \vee \neg(p = q) \wedge \dots \wedge \dots$

CS5219 2007-08 by Abhik

35

## Other stuff

- Counter-example guided Abstraction refinement (additional reading)
  - - by Edmund Clarke et. al, CAV 2000.
  - <http://www-2.cs.cmu.edu/~emc/papers.htm>
  - One of the first papers to develop abstraction refinement. Try summarizing it if you are interested.
- Regular reading appears in Lesson Plan.

CS5219 2007-08 by Abhik

36

## Try it out – (1)

- Consider the program
  - $x = 0; x = x + 1; x = x + 1;$
  - $\text{if } (x > 2)\{\text{error}\}$
- Suppose we want to prove that the ``error" location is never reached, that is, any trace reaching ``error" is a counter-example. Show that the predicate abstraction  $x > 2$  is insufficient to prove this property. You need to construct the abstract transition system for this purpose.

CS5219 2007-08 by Abhik

37

## Try it out – (2)

- Refine your abstraction  $\{x > 2\}$
- by traversing the counter-example obtained.
- Show and explain all steps. Your refined abstraction should be sufficient to prove the unreachability of the ``error" location – i.e. all spurious counter-examples should have been explained by the refined predicate abstraction.

CS5219 2007-08 by Abhik
