Flow in a pipe The hard real-time environment **Engine control** The design challenge

Controlling pipe flow

A simple system (From Kopetz):

(日)

Examples of RT systems (Kopetz) The hard real-time environment

Flow in a pipe Engine control

Controlling pipe flow

The system is supposed to work as follows:

The design challenge

- Maintain a given flow set point (rate of flow) despite changing environmental conditions - note:
 - Varying level of the liquid in the vessel.
 - temperature of the fluid (affecting its viscosity)
- The computer controls the plant by setting the position of the control valve.
- Flow sensor is used to determine the effect of the control.

Examples of RT systems (Kopetz)

The hard real-time environment The design challenge Flow in a pipe Engine control

Controlling pipe flow

But note that:

Actuators also have sensors to monitor the effect of control actions:

- The position of the control valve
- Two limit switches
 - completely open
 - completely closed
- Often 3-7 sensors for every actuator (not just single sensor/actuator).

Examples of RT systems (Kopetz)

The hard real-time environment The design challenge Flow in a pipe Engine control

Controlling pipe flow

Stability of control is a main issue (Separate topic):

- Output action by the controller will affect the environment after a delay. Observing the effect on the environment will involve a delay introduced by the sensor.
- Measure or derive these delays to implement the temporal control structure...

Examples of RT systems (Kopetz)

The hard real-time environment The design challenge Flow in a pipe Engine control

(Car) Engine control

The internal combustion engine

Flow in a pipe Engine control

(Car) Engine control

The system is supposed to work as follows:

• Calculate the amount of fuel and the moment at which this fuel must be injected into the combustion chamber.

• Fuel amount and injection time depend on:

- Intentions of the driver (position of the accelerator pedal)
- Current load on the engine
- Temperature of the engine
- The position of the piston in the cylinder...

Examples of RT systems (Kopetz) The hard real-time environment

The design challenge

Flow in a pipe Engine control

(Car) Engine control

The dynamics of this system:

- The position of the piston indicated by the measured angular position of the crankshaft.
 - Precision required: 0.1 degree
- At 6000 rpm, 10 msecs for each 360 degree rotation.
- Temporal accuracy (sensing when the crankshaft has passed a particular position):
 - Precision required:3 microseconds

10 75

Flow in a pipe Engine control

(Car) Engine control

The dynamics:

- Fuel injection by opening a solenoid valve:
 - Delay from the time "open" command issued by the computing system and the time at which valve opens:
 - hundreds of microseconds!
 - Changes depending on environment (temperature...)
 - This delay is measured each cycle and used to compute when the next "open" command to be issued so that fuel is injected at the right time.
- Extremely precise temporal control is required.
 - Incorrect control can damage the engine!
- Up to 100 concurrently executing software tasks must run in tight synchronization.

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

3 The design challenge

Notions of the challenge

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

A first cut

Three areas for overall requirements:

• Functional

- Data collection and signal conditioning
- Alarms and monitoring
- Control algorithms
- User interface

• Temporal

- Sampling rates and accuracy
- Dead time, jitter, latency
- Dependability/safety

イロト イヨト イヨト イヨト

) 👮 NUS

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Data collection terms and concepts:

- Real time entity: A significant named state variable $\langle Name, Value \rangle$.
- Continuous RT entity: Can be observed at any point in time (pressure)
- Discrete RT entity: Can be observed only between specified occurrences of interesting events (rotation time)
 - If ⟨N, v⟩ is observed at time t and used at time t', then maximum error (v' – v) depends on temporal accuracy (Δ) and maximum gradient of N during this interval.
 - If the gradient is high then △ must be small and tasks using N must be scheduled often!

*

US

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Data collection terms:

- RT Image:
 - Current picture of an RT entity.
 - $\langle Name, time of observation, Value \rangle$

• Accuracy:

- Value (v accuracy)
- Temporal (Δ-accuracy)

イロト イヨト イヨト イヨト

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Data collection terms:

- An RT image is temporally accurate only for a limited time interval.
 - Fast-changing RT entity implies short accuracy for the RT image.
- Only temporally accurate T images must be used in computations.
- Real time data base: All RT entities.
 - This DB must be updated periodically (time-triggered) or immediately after a state change of the RT entity (event-triggered).

< D > < B > < E > < E</p>

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Data collection, Temporal accuracy definition:

 $\langle N, t, v \rangle$ is Δ -accurate if the value of N was v at some time in the interval $(t - \Delta, t)$.

RT image	Maximum change	V-accuracy	\triangle -accuracy
Piston Position	6000rpm	0.1degrees	3μ sec
Accelerator pedal	100%/sec	1%	10msec
Engine load	50%/sec	1%	20msec
Oil temperature	10%/min	1%	6sec

イロト イヨト イヨト イヨト

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Signal conditioning:

- The processing steps needed to convert sensor measurements to RT images.
- Sensor produces a raw signal value: (voltage, pressure, ?)
- Collect a sequence of raw signal values and apply an averaging algorithm to reduce measurement error.
- Calibrate and transform to standard measurement units.
- Check for plausibility (sensor error).

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Alarm monitoring:

- Continuously monitor RT entities to detect abnormal process behaviors.
- When an RT entity's value crosses a pre-set alarm threshold: alarm
- Malfunctioning usually produces an alarm shower.
 - Rupture of a pipe
 - pressure, temperature, liquid levels..
- Must identify primary event.

(日) (四) (三) (三)

NUS

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Alarm monitoring:

- Alarms must be recorded in an alarm log with the time of occurrence of the alarms.
- Time order useful for eliminating secondary alarms.
- Complex plants use knowledge-based systems to assist in alarm analysis.
- Predictable behavior during peak-load alarm situations is vital!
- Performance in rare-event situations is hard to validate in real time systems:
 - Meltdown in nuclear power plant!
- Formal verification!

US

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Control algorithms:

- Design (and implement) control algorithms to calculate set points for the actuators (to enforce control).
 - Sample the values of RT entities.
 - Execute the control algorithm to calculate the new set points.
 - Output the set point signals to the actuators.
 - Take into account delays, and compensate for random disturbances perturbing the plant.
- Warning: Fuzzy controllers not OK for hard RT

< D > < B > < E > < E</p>

10 A)

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements

Man-machine interface:

- Inform the operator of the current state of the controlled object.
- Oritical sub-system:
 - Quality, quantity and format of the information presented requires careful engineering. (Therac-25)
 - Protocols for the interface especially in alarm situations are crucial.
- Many computer-related disasters in safety-critical real time systems have been traced to faults at the man-machine interface.
 - Separate topic!

US

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Functional requirements:

Temporal:

- Stringent requirements come from the control loop:
 - The delay between change in the state of the plant (from the desired values) and the correction action should be less than △.
- Man-machine interface timing requirements are less stringent.
- The sampling rate must be high enough and the execution of the control loop fast enough to minimize △.

< D > < B > < E > < E</p>

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Temporal requirements

Deadtime:

Definition: The delay between the observation of the RT entity and the start of the reaction (control action) of the plant.

- Dead time = delay(computer) + delay(plant)
- delay(computer) = execution time of the control loop.
- delay(plant) = the inertial delay; time of arrival of the actuating signal and the change in the state.

< D > < B > < E > < E</p>

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Temporal requirements:

The important things are to:

- Minimize dead time!
- Minimize latency jitter:
 - max(delay(computer)) min(delay(computer))
- Minimize error detection latency:
 - loss or corruption of a message, failure of a node etc. should be detected within a short time with high probability.

< D > < B > < E > < E</p>

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Dependability requirements

Terms:

Reliability:

• Failure rate λ = failures/hour, $\frac{1}{\lambda}$ = MTTF: Mean Time To Failure. 10⁻⁹ failures/hour: ultrahigh reliability requirement

Maintainability:

- Time required to repair a system after a benign failure.
- For maintainability one needs a number of Smallest Replaceable Units connected by Serviceable interfaces.
- Plug is serviceable but less reliable than solder connection.

Reliability and maintainability are in conflict. Mass consumer products focus on reliability at the cost of maintainability.

(日)

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Dependability requirements

Terms:

Availability

 The fraction of the time the system is ready to provide the service.

Security

prevent unauthorized access to information and services.

Notions of the challenge

< D > < B > < E > < E</p>

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Before TTA there was the CAN bus

Controller Area Network (CAN) from Wikipedia:

- CAN: a broadcast, differential serial bus standard,
- Developed in the 1980s by Bosch, (Cars!)
- Designed to be robust in electromagnetically noisy environments (Cars)
- The messages it sends are 8 data bytes max, protected by a CRC-15 (polynomial 0x62CC) that guarantees a Hamming bit length of 6 (so up to 5 bits in a row corrupted will be detected by any node on the bus).
- Bit rates up to 1 Mbit/s are possible at networks length below 40 m.

TTA systems are intended to have much larger upper bounds (Also Bosch!).

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

(As seen before) TTA architecture...

Nodes communicate using CNI, using a TTP

- All the TTPs in a cluster know this schedule.
- All nodes of a cluster have the same notion of global time.
- Fault-tolerant clock synchronization.

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

MCU for FlexRay

Sample MicroController Unit:

Hugh Anderson

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

MCU for FlexRay

Short technical specs:

- 32 bit pipelined RISC CPU, single cycle instruction execution, 512KB flash
- Lots of I/O ... even 10-bit A/D channels
- Lots of timers
- Sample software in development kit includes production quality TT protocol stack, sample code and scheduler...

3 The design challenge

Notions of the challenge

< D > < B > < E > < E</p>

The main idea

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

The distributed RT computing system performs a multitude of functions concurrently:

- Monitoring RT entities
 - values and rate of change of values.
- Detecting alarm conditions
- Execution of the control algorithms
- Driving the man-machine interface.

(I)

The main idea

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Constraint on the behaviour of these nodes:

- Different nodes execute different functions.
- But all nodes must process all events in the same consistent order.
- More generally, all must have the same view of the times at which interesting events have happened.
- A global time base is needed.

イロト イヨト イヨト イヨト

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks in computers

The hardware:

- Clocks in computers contain a counter a physical oscillation mechanism that periodically generates an event (microtick) that increments the counter.
- The duration between two consecutive microticks is the granularity of the clock.

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

They are not perfect 10^{-2} to 10^{-7} secs/sec...

A clock drift disaster: Feb. 25, 1991:

- Accumulated drift over a 100 hour continuous operation (never before experienced) was nearly 343 msecs.
- This lead to a tracking error of 687 meters causing an incoming Scud missile to be declared a false alarm.
- 29 dead and 79 injured. Bug was fixed the next day.

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

All sorts:

- Global (universal) standard reference clock. (UTC/GMT)
- Have clocks for the nodes, and ensure that the local physical clocks stay locally and globally synchronized.
- NTP? Marzullo's algorithm smallest interval consistent with largest number of sources (200?µsec accuracy)
- GPS time:

🌹 US

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

Imagine a (perfect) reference clock:

- In perfect agreement with UTC (!)
- f frequency and hence $g = \frac{1}{f}$ granularity
- If *f* is large (10¹⁵) then digitization error is small.

Time stamps

- Whenever an event e occurs, an omniscient observer (assume!) records the current reference clock time (i.e. the value of its counter) and generate this value as the time stamp of e.
- t(e): the time stamp of the event e.

(日) (四) (三) (三)

JUS

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

Clock definitions

- drift: the frequency ratio between a clock and a reference clock (over a particular time segment). The perfect value is 1.
- offset: The term offset refers to the time difference between the microticks of two clocks measured in terms of the microticks of the reference clock.
- precision: the maximum offset found between a set of clocks measured in terms of the microticks of a reference clock.
- accuracy: refers to the maximum offset between a clock and the reference over a particular period of interest.

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

Maximum offset occurs at tick 3. Precision is 3 microticks

(日)

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

Clock A is running fast, clock B slow:

Maximum offset of A occurs at A's tick 3, which occurs at 13 microticks of the reference clock (an offset of 2 microticks). The maximum offset of B occurs at B's tick 3, which occurs at 16 microticks of the reference clock (an offset of 1 microticks). The accuracy of the collection with respect to the reference is 2 microticks.

3

ŬS

Requirements for hard real-time systems Time triggered architecture example Clocks and Synchronization

Clocks

The term granularity refers to the time between two ticks of the clock:

Assume we have a collection of two clocks A and B whose precision is 10 msecs and whose global time granularity is 8 msecs. It is possible for B to report that events *e* and *e'* occur at the same time, although A reports that the events occured one after the other.

B US

Notions of the challenge

Outline

Examples of RT systems (Kopetz)

- Flow in a pipe
- Engine control

2 The hard real-time environment

- Requirements for hard real-time systems
- Time triggered architecture example
- Clocks and Synchronization

3 The design challenge

Notions of the challenge

Image: A matrix

Notions of the challenge

The Design Challenge

Two approaches:

- Derive a model of the closed system:
 - Specification/requirements
 - Timing
 - Notion of physical time
- Design and implement:
 - a distributed, fault-tolerant, optimal real time computing system so that the closed system meets the specification/requirements.

< D > < B > < E > < E</p>

Notions of the challenge

The Design Challenge

Structural elements:

- Each computing node will be assigned a set of tasks to perform the intended functions.
- Task :
 - Execution of a (simple) sequential program.
 - Read the input data
 - The internal state of the task (include RT profiles)
 - Terminate with production of results and updating internal state of the task.
- The (real time) operating system provides the control signal for each initiation of the task.

< D > < B > < E > < E</p>

Notions of the challenge

The Design Challenge

Properties for simple tasks:

- No synchronization point within the task.
- Does not block due to lack of progress by other tasks in the system.
- But can get interrupted (preempted) by the operating system.
- Total execution time can be computed in isolation.
- The Worst Case Execution Time of task over all possible relevant inputs.
 - Correct estimate of WCET is crucial for guaranteeing real time constraints will be met.

Notions of the challenge

The Design Challenge

Properties for complex tasks:

- Contains blocking synchronization statement(s):
 - wait semaphore operation.
 - receive message operation.
- Must wait till another task has updated a common data structure:
 - Data dependency
 - Sharing
- Must wait for input to arrive.
- WCET of a complex task can not be computed in isolation.

Notions of the challenge

The Design Challenge

For all tasks:

- There will be tasks that are triggered by exceptions, interrupts and alarms.
- There will be tasks that need to be executed periodically.
- These tasks may have precedence relationships.
- These tasks may have deadlines.
- These tasks may share data structures.
- They may have to execute on the same processor.
- We must schedule!

10 A)
