Midterm Exam

- Don't Panic.
- The midterm contains four problems (and one just for fun). You have 100 minutes to earn 100 points.
- The midterm contains 16 pages, including this one and 4 pages of scratch paper.
- The midterm is closed book. You may bring one double-sided sheet of A4 paper to the midterm. (You may not bring any magnification equipment!) You may not use a calculator, your mobile phone, or any other electronic device.
- Write your solutions in the space provided. If you need more space, please use the scratch paper at the end of the midterm. Do not put part of the answer to one problem on a page for another problem.
- Read through the problems before starting. Do not spend too much time on any one problem.
- Show your work. Partial credit will be given. You will be graded not only on the correctness of your answer, but also on the clarity with which you express it. Be neat.
- You may use any algorithm given in class without restating it—simply give the name of the algorithm and the running time. If you change the algorithm in any way, however, you must provide complete details.
- Good luck!

Problem 1. True, False, and Explain

This problem consists of a set of true/false questions. For each question, circle true or false and briefly (in *at most* one sentence) explain your answer.

Problem 1.a. Graph sketches. For the following three questions, assume $G = (V, E)$ is a graph that is given to you as a stream of edge additions and removals (i.e., it is presented as a stream in the usual way for this class).

In class we described an algorithm that uses a collection of (streaming) L0-samplers to decide whether a graph is connected. In each of the following three questions, assume you use the *exact same* data structure as for determining connectivity, stopping immediately after the stream is complete (and before the connectivity computation is performed). We call the data structure constructed in this way **a graph sketch**.

Using a graph sketch, once the stream is completed, you can use the graph sketch to find a spanning tree of the graph G (if it is connected).

TRUE **FALSE**

Explanation:

Using a graph sketch, once the stream is completed, you can use the graph sketch to answer any one query of the form "Is edge (u, v) in the graph G?"

TRUE **FALSE**

Explanation:

Using a graph sketch, once the stream is completed, you can use the graph sketch to answer any one query of the form "Given a set of nodes $U \subseteq V$, is there any outgoing edge from the set U, i.e., is there any edge (u, v) where $u \in U$ and $v \notin U$?"

TRUE **FALSE**

Explanation:

Problem 1.b. Sampling. The following three questions are related to sampling from either a graph or an array.

Assume you are a given a graph $G = (V, E)$ with n nodes and m edges. You choose a random node in the graph $u \in V$ and count the number of neighbors of u. Let X be the random variable representing the number of neighbors of the randomly chosen node. Then $\mathrm{E}[X] = m/n$.

TRUE **FALSE**

Explanation:

Assume you are given an arbitrary array $A[1..n]$ where each $A[i] \in [1..M]$ and $M > 10n$. Let

$$\bar{a} = \sum_{i=1}^{n} \frac{A[i]}{n}$$

be the average value of the array. Choose a random $i \in [1..n]$, and let X be the random variable representing $A[i]$. Then $\Pr[X \geq 4\bar{a}] \leq 1/4$.

TRUE **FALSE**

Explanation:

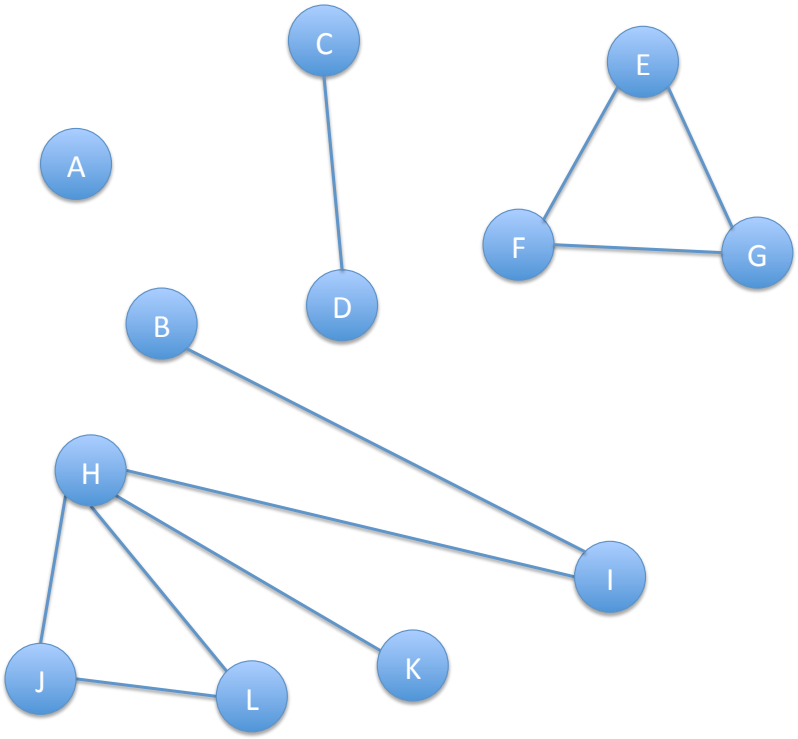
Assume you are given an arbitrary array $A[1..n]$ where each $A[i] \in [1..M]$ and $M > 10n$. Let

$$\bar{a} = \sum_{i=1}^{n} \frac{A[i]}{n}$$

be the average value of the array. Choose a random $i \in [1..n]$, and let X be the random variable representing $A[i]$. Then $\Pr[X \leq \bar{a}/4] \leq 1/4$.

TRUE **FALSE**

Explanation:



Problem 2. Be the computer.

Problem 2.a. In this problem, you will execute the algorithm for finding the approximate number of connected components (using sampling) on the graph above, which has $n = 12$ nodes and maximum degree $d = 4$. Assume that $\epsilon = 1/2$. Use a version of the algorithm that succeeds with constant probability (e.g., probability 2/3).

During the execution, whenever you need to choose a random node in the graph, use the following sequence as your "random number generator":

C, K, F, D, C, K, F, D, C, K, F, D, C, K, F, D, C, K, F, D, C, K, F, D, C, K, F, D, C, K, F, D, ...

For example, the first time you need to choose a random node, use node C. The second time you choose a random node, use node K. Etc. If you run out of random nodes, then repeat the same sequence again. (Notice that this "random number generator" is not very random, and hence your execution may or may not find the "right" answer!)

Outer loop. The algorithm for finding the approximate number of connected components has an outer loop that determines the sample size. As a function of ϵ, n, and d, how many times do you execute the outer loop? (Use big-O notation.)

Loop count (big-O): [ ]

Now compute the precise number of times (i.e., no big-O notation, no variables) that you will execute the outer loop. The constant depends on the probability of success, so there is no single correct value; as long as you choose something reasonable, you will get this part correct. However, to execute the algorithm and determine the final answer, you need to fix a number. (Remember, $\epsilon = 1/2$.)

Loop count (exact): [ ]

Accumulated value. As the algorithm progresses, it accumulates a certain *sum* which is increased after every iteration of the outer loop. List below the value of the sum after the first four iterations. (Your execution may well consist of more than 4 iterations. Here we only ask about the first four iterations. **Explain briefly, to the right, how the new sum was calculated.** (You may use fractions; there is no need to generate a decimal value.)

After iteration 1: [ ]

After iteration 2: [ ]

After iteration 3: [ ]

After iteration 4: [ ]

Final answer. What is the *sum* after all the iterations is complete? What is the final number of connected components calculated by the algorithm? Give the precise answer: do **not** round to the nearest integer.

Final sum: [ ]

Number of connected components calculated: [ ]

Problem 2.b. Now consider the problem of finding the weight of the minimum spanning tree. Assume you have a graph with $n = 12$ nodes, maximum degree $d = 4$, and where all the edges have either weight 1 or weight 7. (The graph in this part is unrelated to the graph in the previous part.)

Recall that G_i is the graph below containing only edges of weight $\leq i$. Assume that graph G_1 has six connected components and graph G_7 has one connected component.

What is the weight of the minimum spanning tree? (You do not need to execute any specific algorithm from class. You do need to give the exact answer.) Explain your calculation briefly below.

Weight of MST: [ ]

Problem 3. Types of friends

Let $G = (V, E)$ be an undirected, unweighted graph representing a new social network: each node in the graph represents a person, and each edge (u, v) represents friendship between u and v. Assume there are n nodes and m edges. Each edge (u, v) has a *type*, for example, a friendship might be "family," or "close friend," or "high school friend," etc. (See the example on Page 9.) Let $t(u, v)$ be the type of edge (u, v). Assume every type is represented as an integer in the range $[1, T]$. Assume that $T = m$.

You are given the edges and their types as a stream (i.e., each item once, in arbitrary order)

$$(u_1, v_1, t_1), (u_2, v_2, t_2), \ldots, (u_m, v_m, t_m)$$

Each edge (and its associated type) will appear *exactly once* in the stream.

The goal is to determine the most common types of friendships in your network. For example, you might discover that "complete stranger" is the most common type of friendship!

More formally, given an integer k (that will be a parameter for your algorithm), your algorithm should, with probability at least 2/3, return a set of types containing:

- all the types t such that at least m/k edges have type t;
- no type t such that fewer than $m/(2k)$ edges have type t.

See the example on Page 9. In this problem (below and on the next page), you will describe an algorithm to solve this problem. As in all streaming algorithms, your primary goal is to use as little space as possible.

Describe briefly, in 1-2 sentences, the main idea behind your algorithm:

How much space does your algorithm use? (Give your answer as a function of n, m, and k. Use big-O notation.)

Space: [ ]

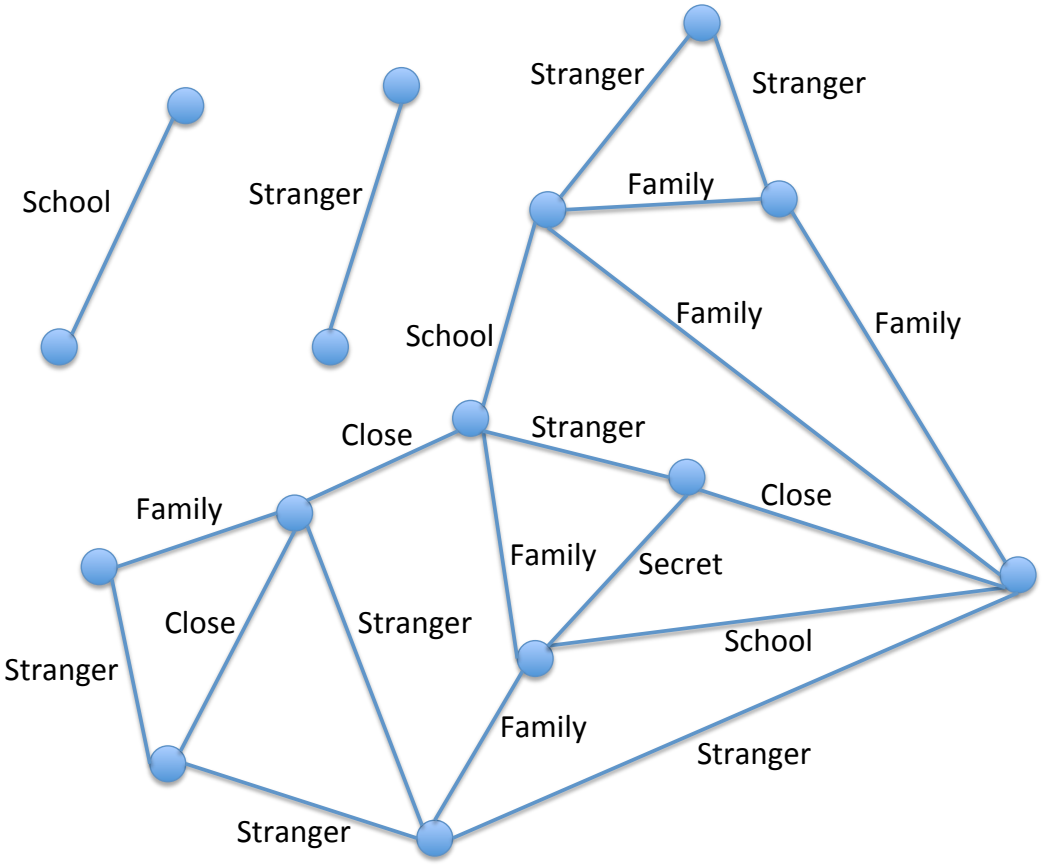
What is the update time for processing an edge in the stream? (Give your answer as a function of n, m, and k. Use big-O notation.)

Update time: [ ]

What is the query time for calculating the set of types, once the stream is complete? (Give your answer as a function of n, m, and k. Use big-O notation.)

Query time: [ ]

(Briefly) describe any additional details of your algorithm and prove that it computes the right answer in the specified time and space:



Example for Problem 3: In this example, we have a graph with 21 edges. There are several different types of friendship edges: Family, Close, School, Stranger. There are 6 family edges, 3 close edges, 3 school edges, and 8 stranger edges.

When your algorithm runs with $k = 3$, it should return any friendship type that appears on at least 7 edges. Hence in this case, it *must* return "stranger." The algorithm may optionally return any friendship type that appears on at least 3.5 edges. Hence in this case, it *may* return "family." It may not return any of the other friendship types, as they are not sufficiently common.

Problem 4. Three-way elections.

Imagine you have an election where Alice, Bob, and Collin are running for President of Probabilityland. Let V be an array representing n votes: $V[1\,..\,n]$ where each $V[i] \in \{A, B, C\}$ represents a vote for Alice, Bob, or Collin.

Let x_A be the number of votes for Alice, i.e., the number of A's in the array. Let x_B be the number of votes for Bob, i.e., the number of B's in the array. We do not care about Collin. Collin is not allowed to be president.

The goal of this problem is to decide as efficiently as possible whether there are more votes for Alice or Bob in the array. (Remember, we do not care about Collin.) For a given parameter ϵ, give an algorithm with the following properties:

- If $x_A - x_B \geq \epsilon n$, return Alice, with probability at least 2/3.
- If $x_B - x_A \geq \epsilon n$, return Bob, with probability at least 2/3.
- Otherwise, return either Alice or Bob. (The election is too close to call.)

For example, assume $\epsilon = 1/4$, $n = 12$, and array B is as follows:

$$V = [A, B, A, B, A, B, C, B, B, C, B, C]$$

Here, $x_A = 3$ and $x_B = 6$. Since $\epsilon n = 3$, we conclude that $x_B - x_A \geq 3$ and return Bob. However, if there were one fewer vote for Bob, then we could return either Alice or Bob.

Your algorithm should run in sublinear time (e.g., $o(n)$ time), looking at as few votes as possible. That is, you should not actually compute the exact values of x_A and x_B. For partial credit, you can assume that Collin gets zero votes, i.e., all the votes in the array are either A or B.)

Describe briefly, in 1-2 sentences, the main idea behind your algorithm:

What is the query complexity of your algorithm? (That is, how many votes in the array does it look at? Give your answer as a function of n and ϵ. Use big-O notation.)

Queries: [ ]

(Briefly) describe any additional details of your algorithm and prove that it computes the right answer in the specified time:

Problem 5. (Just for fun!) [0 points]

Last week, I received an anonymous invitation to a strange party at a secret location. I went with my wife. There we met 4 other couples, who had also received anonymous invitations. Thus were ten of us at the party, each of whom had come with a partner.

Luckily, some of us at the party already knew each other. We each shook hands with the people we did not know. (People who already knew each other did not shake hands.) We all were wondering why we were here. To gain some information, I asked each of the nine other people in the room how many hands they had shook. Surprisingly, I got nine different answers! Each person had shaken a different number of hands!

How many people at the party did my wife not know before the party?
