Review

- Suppose a doctor can work in several hospitals and receives a salary from each one. Moreover, suppose each doctor has a primary home address and several doctors can have the same primary home address. Is R(doctor, hospital, salary, primary_home_address) normalized?
- What are the functional dependencies?
 doctor, hospital → salary
- doctor, hospital → salary
 doctor → primary_home_address
- doctor, hospital → primary_home_address
- The key is (doctor, hospital). Since doctor (in second FD) is a subset of the key, the table is not normalized.
- A normalized decomposition would be:
 R1(doctor, hospital, salary)
 - R2(doctor, primary_home_address)

Disk, Storage & Access Methods

2

- Costs too much? Not any more
 \$100 will buy you either 1 GB of RAM or 500 GB of disk today.
- *Main memory is volatile*. We want data to be saved between runs.
- Data is also increasing at an alarming rate. – "Big-Data" phenomenon
- Memory error

CS5208

- Larger memory means higher chances of data corruption
- Typical storage hierarchy:
- Main memory (RAM) for currently used data.
- SSD/Flash memory (between RAM and Disk)
- Disk for the main database (secondary storage).
- Tapes for archiving older versions of the data (tertiary storage).
 CS5208

Secondary storage device of choice.
Main advantage over tapes: *random* access vs. sequential.
Data is stored and retrieved in units called *disk blocks* or *pages*.
Unlike RAM, time to retrieve a disk page varies depending upon location on disk.

Therefore, relative placement of pages on disk has major impact on DBMS performance!

Disks

5

Accessing a Disk Page

- Time to access (read/write) a disk block:
 - seek time (moving arms to position disk head on track)
 - rotational delay (waiting for block to rotate under head)
 - transfer time (actually moving data to/from disk surface)
- Seek time and rotational delay dominate.
 - Seek time varies from about 0.3 to 10msec
 - Rotational delay varies from 0 to 4msec
 - Transfer rate is about 0.08msec per 8KB page
- Key to lower I/O cost: reduce seek/rotation delays!

CS5208

Improving Access Time of Secondary Storage

- · Organization of data on disk
- · Disk scheduling algorithms
- Multiple disks or Mirrored disks
- · Prefetching and large-scale buffering

8

Algorithm design

CS5208

An Example · How long does it take to read a 2,048,000-byte file that is divided into 8,000 256-byte records assuming the following disk characteristics? average seek time 18 ms track-to-track seek time 5 ms rotational delay 8.3 ms 16.7 ms/track maximum transfer rate bytes/sector 512 sectors/track 40 tracks/cylinder 11 tracks/surface 1,331 1 track contains 40*512 = 20,480 bytes, the file needs 100 tracks (~10 cylinders).
