Java Threads

Multithreaded execution is an essential feature of the Java platform. Every application has at least one thread — or several, if you count “system” threads that do things like memory management and signal handling.

From the application programmer’s point of view, you start with just one thread, called the main thread. This thread has the ability to create additional threads.

Parallelism is not necessary, but possible. The threads can time-share on a processor.

Managing Thread objects

Each application thread is an instance of the class Thread.

In the programming style I describe here:

- the application directly controls thread creation and management by instantiating the Thread class whenever necessary.
- An application that creates an instance of Thread must provide the code that will run in that thread. There are two ways to do this:
  - use the Runnable interface
  - create a subclass of the Thread class.

Starting a Thread (1)

```java
public class HelloRunnable implements Runnable {
    public void run() {
        System.out.println("Hello from a thread!");
    }
    public static void main(String args[]) {
        new Thread(new HelloRunnable()).start();
    }
}
```

Runnable interface contains a single method `run()`, containing code to be executed.

Re-define the `run()` method and pass it to the thread constructor.

Starting a Thread (2)

```java
public class HelloThread extends Thread {
    public void run() {
        System.out.println("Hello from a thread!");
    }
    public static void main(String args[]) {
        new HelloThread().start();
    }
}
```

Each thread has a priority

- Initial priority: inherited from its parent thread
- `setPriority(int newPriority)`

When multiple threads running on the same processor

- Ready thread with highest priority `get` executed
- “Randomly” select among threads with same priority
Common programming mistakes

Thread myThread = new Thread(MyRunnable());
myThread.run();

Calling thread will execute the run() method
• Treated as normal function call
• No new thread is created
• Not desirable in most situations

Thread myThread = new Thread(MyRunnable());
myThread.start();

A new thread is created (run() is executed in this new thread)

A sleeping thread

public class SleepMessages {
    public static void main(String[] args) throws InterruptedException {
        String importantInfo[] = { "Mares eat oats", "Does eat oats", "Little lambs eat ivy", "A kid will eat ivy too" };
        for (int i = 0; i < importantInfo.length; i++) {
            //Pause for 4 seconds
            Thread.sleep(4000); //Print a message
            System.out.println(importantInfo[i]);
        }
    }
}

Thread.sleep causes the current thread to suspend execution for a specified period.
This is an efficient means of making processor time available to the other threads of an application or other applications that might be running on a computer system.

Stopping Threads

Thread normally terminates by returning from its run() method

Deprecated methods: stop(), suspend(), destroy() etc.
• Unsafe, don't use
• Use (shared) variables to control thread termination if necessary

The join method allows one thread to wait for the completion of another
t.join();
causes the current thread to pause execution until it's thread terminates.

An Example

public class ThreadExample {
    public static void main(String[] args){
        System.out.println(Thread.currentThread().getName());
        for(int i=0; i<10; i++){
            new Thread() {
                public void run(){
                    System.out.println("Thread: " + getName() + " running");
                }
            }.start();
        }
    }
}

1. What does the above example do?
2. How many threads will be created?
3. What will be the exact printout?

Thread Communication

• Two common modes of thread communication in parallel / concurrent programming
  • Shared memory
  • Message passing

In this course, we study the Java shared memory communication style where threads read and write shared objects. This requires synchronization mechanisms to ensure safe and “correct” accesses to the objects.

Message passing is also available in java
• Refer to Textbook, Chapter 10

Two problems in Concurrent Programming

• Race conditions
  • Two or more threads access the shared data simultaneously
  • Solution: lock the data to ensure mutual exclusion of critical sections

• Deadlock
  • Two threads are waiting for each other to release a lock, or more than two processes are waiting for lock in a circular chain.
Interference between threads

class Counter {
    private int c = 0;
    public void increment() {
        c++;
    }
    
    public void decrement() {
        c--;
    }
    
    public int value() {
        return c;
    }
}

Counter c = new Counter();
public class ThreadA extends Thread{
    public void run() { c.increment(); }
}

public class ThreadB extends Thread{
    public void run() { c.decrement(); }
}

Avoiding thread interference – (1)

Java programming provides two basic synchronization idioms: synchronized methods and synchronized statements

public class SynchronizedCounter {
    private int c = 0;
    public synchronized void increment() {
        c++;
    }
    
    public synchronized void decrement() {
        c--;
    }
    
    public synchronized int value() {
        return c;
    }
}

Why synchronized methods?

- It is not possible for two invocations of synchronized methods on the same object to overlap.
- When a synchronized method exits, it makes the object state visible to all threads accessing the object subsequently via synchronized methods

Minor point: Constructors cannot be synchronized, try it! Why??

Synchronized Method and Statements

Synchronized methods lock this object
- Synchronized statements can lock any objects (including this)

    public synchronized void foo() {
        ...
    }

is equivalent to

    public void foo() {
        synchronized(this){ ...
    }

Synchronized statements refer to an object — this refers to the object whose method is being executed.

Needed to avoid generating redundant methods – see example above.

Invoking other object's methods from synch code can be problematic?
Finer-grained concurrency

```java
public class not_together {
    private long c1 = 0;
    private long c2 = 0;
    private Object lock1 = new Object();
    private Object lock2 = new Object();

    public void inc1() {
        synchronized(lock1) {
            c1++;
        }
    }

    public void inc2() {
        synchronized(lock2) {
            c2++;
        }
    }
}
```

Different from using `synchronized(this)`

- `c1` and `c2` are independent, never used together.
- `=>` Updates can be interleaved.

Fine grained locks

```java
class FineGrainLock {
    MyMemberClass x, y;
    Object xlock = new Object(), ylock = new Object();

    public void foo() {
        synchronized(xlock) { //access x here
            //do something - but don't use shared resources
            synchronized(ylock) { //access y here
            }
            ylock = new Object();
            //do something - but don't use shared resources
            ylock = new Object();
        }
    }

    public void bar() {
        synchronized(xlock) {
            synchronized(ylock) {
                //access both x and y here
            }
            ylock = new Object();
            //do something - but don't use shared resources
            ylock = new Object();
        }
    }
}
```

Re-emphasizing Locks

Consider a bank with 10,000 accounts, each with $1000. Bank's asset = $10 million.

Simulate the bank's activity with two threads.

- ATM thread: picks two accounts at random and moves a random amount of money from one account to another.
- Audit thread: Periodically wakes up, and adds all the money in all the accounts.

We should always have $10 million in the bank (Invariant)

ATM Class

```java
class ATM extends Bank implements Runnable{
    public void run(){
        int fromAcc, toAcc, amount;
        while (true){
            fromAcc = (int) random(numAcc);
            toAcc = (int) random(numAcc);
            amount = 1+ (int)random(savings[fromAcc].balance);
            savings[fromAcc].balance -= amount;
            savings[toAcc].balance += amount;
        }
    }
}
```

Auditor Class

```java
class Auditor extends Bank implements Runnable{
    public void run(){
        int total;
        while (true){
            nap(1000);  total = 0;
            for (int i = 0; i < numAcc; i++)
                total += savings[i].balance;
            // print the total
        }
    }
}
```

Fixing the ATM

```java
class ATM{
    synchronized (lock) {
        savings[fromAcc].balance -= amount;
        savings[toAcc].balance += amount;
    }
}
```

By Abhik & Ju Lei
Thread safety without Synchronization

Local Variables - stored in each thread's local stack. Accessed only by one thread, no synchronization needed.

```java
public void someMethod() {
    long threadSafeInt = 0;
    threadSafeInt++;}
```

Volatile Variables

Consider any simple Java stmt, e.g., x=0

Translates to a sequence of bytecodes, not atomically executed.

One way of ensuring atomic execution in Java —

Mark variables as volatile

reads/writes (including get-and-set after Java 5) of volatile variables are atomic (directly update global mem.)

An example with volatile variables

```java
public class StoppableTask extends Thread {
    private volatile boolean pleaseStop = false;
    public void run() {
        while (!pleaseStop) {
            // do some stuff...
        }
        public void tellMeToStop() {
            pleaseStop = true;
        }
    }
}
```

A common bug with volatile

class Counter {
    private volatile int c = 0;
    public void increment() {
        c++;
    }
    public void decrement() {
        c--;
    }
    public int value() {
        return c;
    }
}

Wrong program!!!

```java
int temp;
synchronized (c) {
    temp = c;
    c = temp;
}
```
Volatile Vs. Synchronized

- Summarize on volatile variables
  - Value of volatile variable will never be cached
  - Access (read/write/get-and-set) to the variable is atomic
- Pros
  - Light-weight synchronization mechanism
  - A primitive variable may be declared volatile
  - Access to a volatile variable never block (deadlock)
- Cons
  - Correct use of volatile relies on the understanding of Java memory model (e.g., get-update-set of a volatile variable is not atomic).

Pros
- Light-weight synchronization mechanism
- A primitive variable may be declared volatile
- Access to a volatile variable never block (deadlock)

Cons
- Correct use of volatile relies on the understanding of Java memory model (e.g., get-update-set of a volatile variable is not atomic).

Transfer of Thread Control
- Sometimes, a thread needs certain conditions (on shared objects) to hold before it can proceed
- Method 1: polling/spinning
  - repeatedly locking and unlocking an object to see whether some internal state has changed
  - Inefficient, possible cause of deadlock
- Method 2: wait/notify
  - a thread can suspend itself using wait until such time as another thread awakens it using notify

Wait and notify
- wait(): Waits for a condition to occur. This is a method of the Object class and must be called from within a synchronized method or block.

notify():
- Notifies a thread that is waiting for a condition that the condition has occurred. This a method of the Object class and must be called from within a synchronized method or block.
- Every object inherits from the Object class, hence support wait/notify.

Producer and Consumer Example (1)

```java
class Q {
    //queue of size 1
    int n;
    synchronized int get() {
        System.out.println("Got: " + n);
        return n;
    }
    synchronized void put(int n) {
        this.n = n;
        System.out.println("Put: " + n);
    }
}
```

```java
class Producer implements Runnable {
    Q q;
    Producer(Q q) {
        this.q = q;
        new Thread(this, "Producer").start();
    }
    public void run() {
        int i = 0;
        while(true) {
            q.put(i++);
        }
    }
}
```

Deadlock
- Example
  - threadA:
    synchronized(lock1) {
      synchronized(lock2) {
        ....
      }
    }
  - threadB:
    synchronized(lock2) {
      synchronized(lock1) {
        ....
      }
    }
- The java programming language does not prevent deadlock conditions
  - Programmer has to take care of possible deadlock situation (use conventional techniques/programming patterns for deadlock avoidance)
  - Formal verification (e.g., Promela & Spin)

```java
Producer and Consumer Example (1)
```
Producer and Consumer Example (1)

```java
class Consumer implements Runnable {
  Q q;
  Consumer(Q q) {
    this.q = q;
    new Thread(this, "Consumer").start();
  }
  public void run() {
    while(true) {
      q.get();
    }
  }
}
```

Possible output:

```
Put: 1
Got: 1
Got: 1
Got: 1
Got: 2
Put: 2
Put: 3
Put: 4
Got: 4
```

Producer and Consumer Example (2)

```java
class Q {
  int n;
  boolean valueSet = false;
  synchronized int get() {
    while(!valueSet) {
      try {
        wait();
      } catch(InterruptedException e) {
      }
    }
    System.out.println("Got: "+n);
    valueSet = false;
    notify(); //notify the producer
    return n;
  }
  synchronized void put(int n) {
    while(valueSet) {
      try {
        wait();
      } catch (Exception e) {}
    }
    this.n = n;
    valueSet = true;
    System.out.println("Put: "+n);
    notify();
  }
}
```

public synchronized void getResource (int number) {
    while (1) {
        if (resourcecount + number <= resourcemax) {
            resourcecount += number; break;
        }
        try {
            wait();
        } catch (Exception e) {}
    }
}

public synchronized void freeResource (int number) {
    resourcecount -= number; notifyAll();
}

What purpose does notifyAll() serve here?

```
notifyAll()
```

Notifies all waiting threads on a condition that the condition has occurred.

All threads wake up, but they must still re-acquire the lock.

Thus, one of the awakened threads executes immediately after waking up.

```
notifyAll()
```

Notifies all waiting threads on a condition that the condition has occurred.

All threads wake up, but they must still re-acquire the lock.

Thus, one of the awakened threads executes immediately after waking up.
Beyond Locks

Locks ensure mutually exclusive access.

If there are n resources to be picked up by m > n contenders.

We need a semaphore with a count
initialize count to n (if of resources)
as each resource is acquired, decrement count
as each resource is released, increment count.

Semaphores are not directly supported by Java. But, they can
be easily implemented on top of Java’s synchronization.

Counting Semaphores

```java
class Semaphore {
  private int count;
  public Semaphore(int n) {this.count = n; }
  public synchronized void acquire(){ … }
  public synchronized void release(){ … }
}
```

```java
public synchronized void acquire(){
  while(count == 0) {
    try { wait(); }
    catch (InterruptedException e){
      //keep trying
    }
    count--;
  }
}
```

```java
public synchronized void release(){
  count++;
  notify(); //alert a thread
  //that's blocking on
  //this semaphore
}
```

Using counting semaphores

```java
import java.util.concurrent.Semaphore;

class Count extends Thread{
  static volatile int n = 0;
  static Semaphore s = new Semaphore(1);
  public void run(){
    int tmp;
    for (i =0; i < 10; i++){
      s.acquire();
      tmp = n;  n = tmp +1;
      s.release();
    }
  }
}
```
