

Abstraction Refinement

CS 5219
Abhik Roychoudhury
National University of Singapore

CS5219 2010-11 by Abhik 1

MC

- Model checking is a search based procedure applicable to only finite state systems.
- Extension to infinite state systems (arising out of infinite data domains) handled by abstraction of memory store.
- Requires human ingenuity in choice of the abstract predicates.

CS5219 2010-11 by Abhik 2

Abstraction Refinement

- Given a program P and a property f, very difficult to get the "right" abstraction which will be able to prove f (even if f is true).
- Instead start with a very coarse abstraction and model check the resultant abstract model.
- Counter-example generated may not correspond to any concrete trace of P.
 - Refine the abstract model.

CS5219 2010-11 by Abhik 3

Software Model Checking without Refinement

```

graph LR
    P[Program P] -- Extraction --> M[Finite state Model M]
    User[User provided Predicate store] -.-> M
    M --> MC((Model Checker M |= phi ?))
    MC --> YES[YES, Proved.]
    MC --> NO[NO, Counter-example]
    MC --> Phi[Temporal Property phi]
  
```

CS5219 2010-11 by Abhik 4

... and with Refinement

```

graph LR
    P[Program P] -- Model Extraction --> M[Finite state Model M]
    User[In practice, provides preds.] -.-> M
    M --> MC((Model Checker M |= phi ?))
    MC --> YES[YES, phi Proved.]
    MC --> NO[NO, Counter-example]
    NO --> Refine[Spurious, Refine]
    Refine -- Additional preds --> M
    NO --> Real[Real Counter-example, phi disproved]
  
```

CS5219 2010-11 by Abhik 5

Infeasible paths

$v = 0;$
 if ($v < 0$) then S1
 if ($u < 0$) then S1
 if ($u > 0$) then S2.

$v = 0$
 S1
 S1
 S2

CS5219 2010-11 by Abhik 6

Infeasible paths

for (j=1 to 100) do
 if j%2 == 0 then
 S1...
 else
 S2
endfor

CS5219 2010-11 by Abhik

7

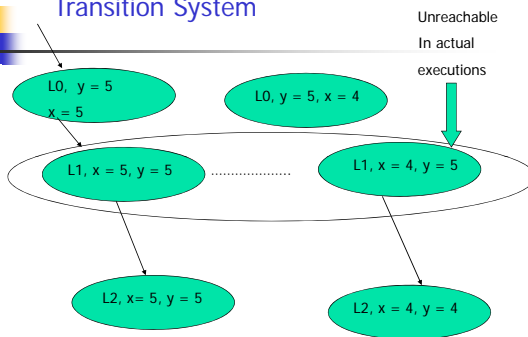

An example program

- L0: $x = 5$
- L1: $y = x$
- L2
- Property $G (pc = L2 \Rightarrow y = 5)$
- Suppose we abstract with $(y = 5)$

CS5219 2010-11 by Abhik

8

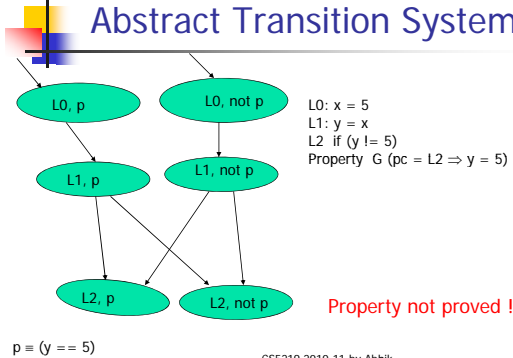

Fragment of Concrete Transition System

CS5219 2010-11 by Abhik

9

Abstract Transition System

CS5219 2010-11 by Abhik

10

Abstract counter-example

- The following can be a counter-example trace returned by model checking
 - $\langle L0, p \rangle, \langle L1, p \rangle, \langle L2, \text{not } p \rangle$
- But this does not correspond to any execution of the concrete program.
- This is a spurious counter-example
- Need to input new predicates for abstraction.

CS5219 2010-11 by Abhik

11

Abstraction refinement

- Generate the new predicates by analyzing the counter-example trace.
- A more informative view of the program's memory store is thus obtained.
- But how to establish a correspondence between the abstract counter-example and the concrete program ?

CS5219 2010-11 by Abhik

12

An Example

- Initially $x == 0$
- L0: while (1) {
- L1: $x++$;
- L2: while ($x > 0$) $x--$;
- L3 }

Property: $AG(pc == L2 \Rightarrow x == 1)$

A locational invariant

CS5219 2010-11 by Abhik

13

Initial Abstraction

No need to traverse further, counter-example trace found.

CS5219 2010-11 by Abhik

14

Counter-example

The predicate p denotes $(x == 1)$

CS5219 2010-11 by Abhik

15

Counter-example verification

- The counter-example may be **spurious** because our abstraction was too coarse.
 - The sequence of statements in the control-flow graph constitute an infeasible path in Control Flow Graph.
 - Not part of any concrete execution trace in the program.
- How to check whether the produced counter-example trace is spurious?
 - Backwards or forwards exact reasoning on the counter-example trace.
 - Backwards reasoning shown now, forwards reasoning later in the lecture.

CS5219 2010-11 by Abhik

16

Exact reasoning

$(L2, x \neq 1) \leftarrow (L1, x \neq 0) \leftarrow (L0, x \neq 0) \leftarrow \text{Initially } (x \neq 0 \wedge x = 0)$
 -- the constraint to hold initially is unsatisfiable.

CS5219 2010-11 by Abhik

17

One step of exact reasoning

What is the weakest constraint on data states that should hold at L1, such that when control moves to L2 (by executing $x++$), the data state at L2 is guaranteed to satisfy $x \neq 1$?

- Weakest pre-condition (WP) computation.
- We repeat the WP computation until we reach the end of the trace OR the constraint accumulated becomes unsatisfiable.
- Corresponds to Real counter-example OR spurious counter-example.

CS5219 2010-11 by Abhik

18

Effect constraint of each statement

$\Psi(X, X')$

e.g. effect constraint of $X++$ is $X' = X + 1$

During backwards reasoning along the trace from the end of the trace

- for every assignment $X = e$, replace X by e in the formula
- for every branch with condition c , conjoin formula with c .

For assignment $X = e$, formula f becomes $f[X \rightarrow e]$
 For branch with condition c , formula f becomes $f \wedge c$

CS5219 2010-11 by Abhik 19

So, what do we know ?

- We are verifying an invariant ϕ against an infinite state system M .
- We abstracted (the data states of) M w.r.t. p_1, \dots, p_k to get $M1$
 - For every trace c_1, c_2, \dots, c_n (statement sequences) in M , there is a trace c_1, c_2, \dots, c_n in $M1$ (not vice-versa)
- Model check $M1 \models \phi$ to
 - Case 1: Success. We have proved $M \models \phi$
 - Case 2: We get a counter-example trace σ_1
 - Need to check whether σ_1 is "spurious"

CS5219 2010-11 by Abhik 20

What is "spurious" ?

- Each trace in M (concrete system) has a corresponding trace with same statement sequence in $M1$ (abstract system).
- A trace in $M1$ may not have a corresponding trace with same statement sequence in M .
- Does the counter-example trace σ_1 in $M1$ have a corresponding trace σ with same statement sequence in M ?
 - If not, then σ_1 is a spurious counter-example

CS5219 2010-11 by Abhik 21

What if spurious ?

- So, we discussed how to check whether an obtained counter-example is spurious.
- If σ_1 is not spurious, then we have proved that M (concrete sys.) does not satisfy ϕ
- If σ_1 is spurious, we need to refine the abstraction of M
 - Original abs: Predicates p_1, \dots, p_k
 - New abs: Preds $p_1, \dots, p_k, p_{(k+1)}, \dots, p_n$

CS5219 2010-11 by Abhik 22

But how do we ...

- ... compute the new preds $p_{(k+1)}, \dots, p_n$?
 - No satisfactory answer, still somewhat active topic of research.
 - All existing approaches are based on analysis of the spurious counter-example trace σ_1
 - Concretize the abstract states of σ_1 to get constraints on concrete data states.
 - But several ways to glean the new predicates from these constraints.
 - We will just look at some possible heuristics.

CS5219 2010-11 by Abhik 23

Our example

pc = L0, p = false

pc = L1 \wedge $x \neq 0$

While(1){

pc = L1, p = false

pc = L1 \wedge $x \neq 0$

x++

pc = L2, p = false

pc = L2 \wedge $x \neq 1$

Clearly, such states should be unreachable in the concrete system.

CS5219 2010-11 by Abhik 24

New predicates

- Based on the spurious trace, we choose another predicate $q = (x = 0)$
 - No clear answer why, different research papers give different heuristic 'justifications'.
- Again abstract the concrete program w.r.t. the predicates
 - $p = (x = 1)$
 - $q = (x = 0)$

CS5219 2010-11 by Abhik

25

New abstract transition system

CS5219 2010-11 by Abhik

26

Final result

- Model checking the new abstract transition system w.r.t.
 - $AG(pc == L2 \Rightarrow x == 1)$
- ... yields no counter-example trace.
- Constitutes a proof of
- $M \models AG(pc == L2 \Rightarrow x == 1)$
- Where M is the transition system corresponding to original program.

CS5219 2010-11 by Abhik

27

Constructing Explanations

- Start from the end (or beginning of the trace)
 - Strongest post condition (SP), [next slide]
 - Or Weakest Pre condition (WP) [discussed]
- Perform exact reasoning at each step until you hit unsatisfiability
- Greedily remove one constraint at a time from the unsatisfiable constraint store until it becomes satisfiable
 - Is that sufficient ?

CS5219 2010-11 by Abhik

28

SP along a trace

- assume($b > 0$) $b > 0$
- $c := 2*b$ $b > 0, c = 2b$
- $a := b$ $b > 0, c = 2b, a = b$
- $a := a - 1$ $b > 0, c = 2b, a = b-1$
- assume ($a < b$) $b > 0, c = 2b, a = b-1, a < b$
- assume ($a = c$) $b > 0, c = 2b, a = b-1, a < b, a = c$
- Conjunction shown with comma.

CS5219 2010-11 by Abhik

29

Choosing predicates

- $b > 0, c = 2b, a = b-1, a < b, a = c$
- Removing $a = b-1$ makes the constraint satisfiable
 - Should we choose it?
- Is it sufficient to choose predicates from the formula which makes the formula uns
- Exercise:** Try to work out the backwards traversal and investigate choices of predicates.

CS5219 2010-11 by Abhik

30

Choosing predicates

- $a := b;$ $a = b$
 - $a := a - 1;$ $a = b - 1$
 - $\text{assume}(a \geq b)$ $a = b - 1, a \geq b$
- If we choose $a = b - 1, a \geq b$ as new refinement it may not suffice.
- The effect of $a := b$ can only be accurately captured by the pred $(a = b)$
- So, we need all predicates whose **transformation** leads to one of the predicates causing unsatisfiability.

CS5219 2010-11 by Abhik

31

Exercise

- Try verifying absence of error in
 - $a := b; a := a - 1; \text{if } (a \geq b) \{ \text{error} \}$
- Using the predicates
 - $\{a \geq b\}$
 - $\{a \geq b, a = b - 1\}$
- Feel free to use forwards or backwards counter-example analysis ...

CS5219 2010-11 by Abhik

32

Additional: Dealing with pointers

```
int *p, *q;
void main(){
  if (*p == 3){
    *q = 2;
    if (*p == 2){
      *p = 3;
      if (*q == 2){
        ERROR
      }
    }
  }
}
```

p may or may not be **aliased** to q

Is the **ERROR** state ever reachable?

CS5219 2010-11 by Abhik

33

Use pointer analysis

- Can p ever alias to q
 - Static analysis, flow insensitive.
- If yes, then need to consider both the aliased and non-aliased cases
 - Corresponding to truth of $p=q$ which is also maintained as a predicate.
 - Infeasible constraint store has disjunction
 - $(p = q \wedge \dots \wedge \dots) \vee (\neg(p = q) \wedge \dots \wedge \dots)$

CS5219 2010-11 by Abhik

34

More details

- Computation of SP
 - Forward simulation of the trace with non-concrete input values.
 - Maintain a variable valuation store as well as constraint store
 - Please check out the reading

CS5219 2010-11 by Abhik

35

Example

$\text{assume}(b > 0)$	$\langle (c, 2b) \rangle$	$b > 0$
$c = 2 * b$	$\langle (c, 2b), (a, b) \rangle$	$b > 0$
$a = b$	$\langle (c, 2b), (a, b-1) \rangle$	$b > 0$
$a = a - 1$	$\langle (c, 2b), (a, b-1) \rangle$	$b > 0 \wedge b-1 < b$
$\text{assume}(a < b)$	$\langle (c, 2b), (a, b-1) \rangle$	$b > 0 \wedge b-1 < b \wedge 2b = b-1$
$\text{assume}(c = a)$	$\langle (c, 2b), (a, b-1) \rangle$	

CS5219 2010-11 by Abhik

36

Try it out – (1)

- Consider the program
 - $x = 0; x = x + 1; x = x + 1;$
 - $\text{if } (x > 2) \{ \text{error} \}$
- Suppose we want to prove that the ``error" location is never reached, that is, any trace reaching ``error" is a counter-example. Show that the predicate abstraction $x > 2$ is insufficient to prove this property. You need to construct the abstract transition system for this purpose.

Try it out – (2)

- Refine your abstraction $\{ x > 2 \}$
- by traversing the counter-example obtained.
- Show and explain all steps. Your refined abstraction should be sufficient to prove the unreachability of the ``error" location – i.e. all spurious counter-examples should have been explained by the refined predicate abstraction.
