

# **M<sup>2</sup>R: Enabling Stronger Privacy in MapReduce Computation**

*Anh Dinh, Prateek Saxena,*

*Ee-Chien Chang, Beng Chin Ooi, Chunwang Zhang*

School of Computing

National University of Singapore

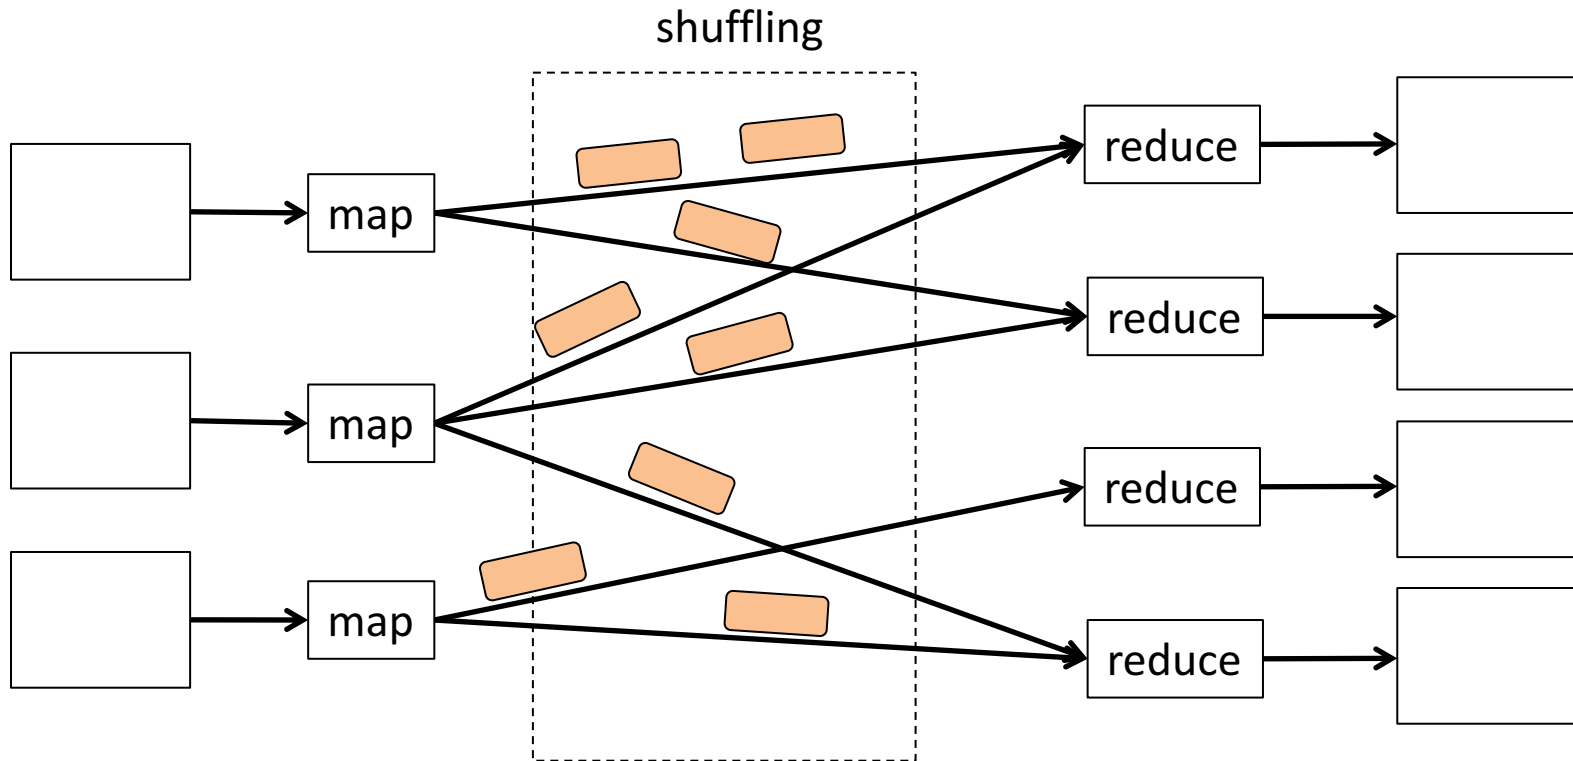

# 1. Motivation

- Distributed computation (MapReduce) on large dataset with Trusted computing.

- Integrity + Confidentiality.
- Applicable in private or public cloud setting.

# Background: MapReduce

- Computation & “shuffling” of  $\langle \text{key}, \text{value} \rangle$  tuples. 
- Phases: Map  $\rightarrow$  Shuffle  $\rightarrow$  Reduce.
- “map” outputs a set of tuples.
- During Shuffling, tuples are grouped according to their key.
- Each “reduce” instance corresponds to a unique key  $k$ . It takes all tuples with the key  $k$  and outputs a set of tuples.

# Background: Hadoop

- Hadoop: software framework written in Java
- $\approx$  190K LOC (Hadoop 0.21.0)
- Consists of MapReduce modules, Hadoop Distributed File System (HDFS), etc.

# Challenge 1: Keep Trusted Code Base small

Application Frameworks

Operating Systems

Hypervisor

Vulnerabilities By Year

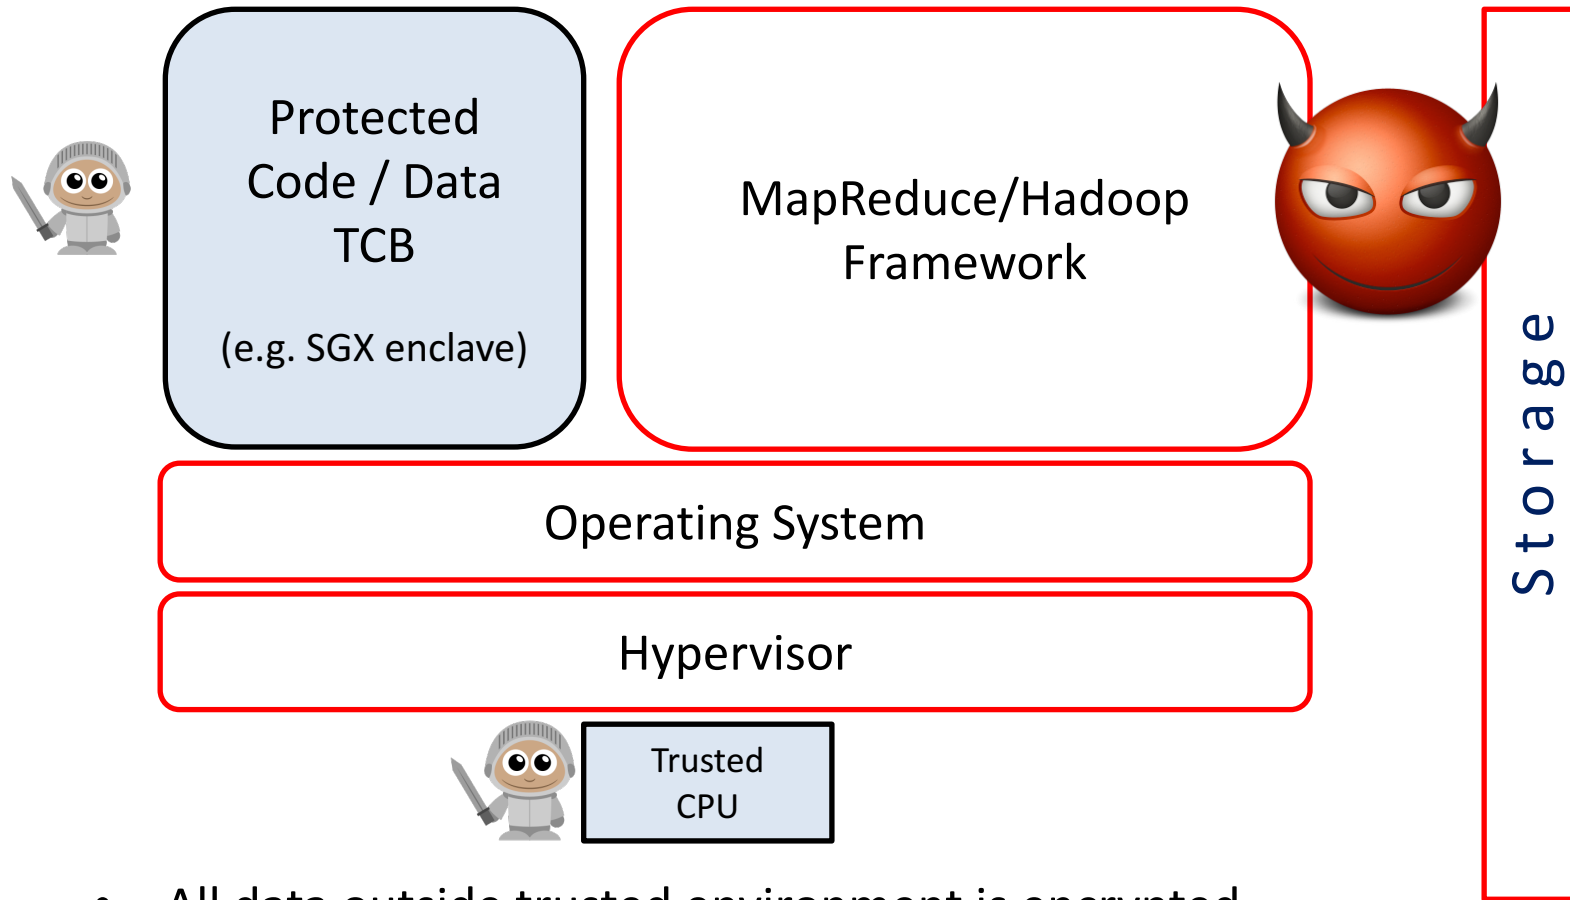

CVEs in Linux [[CVE-DB](#)]

Vulnerabilities By Year

Affected many hypervisors (e.g Xen / KVM) [[CS Report](#)]

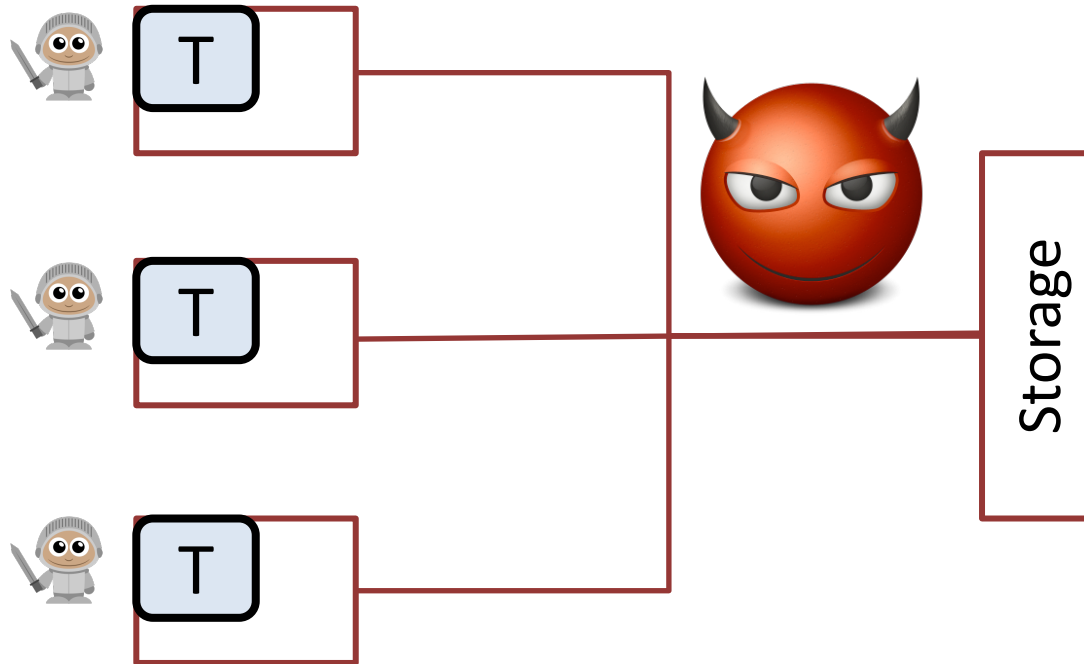

# Challenge 1: Keep TCB small

- All data outside trusted environment is encrypted
- Software-only attack.

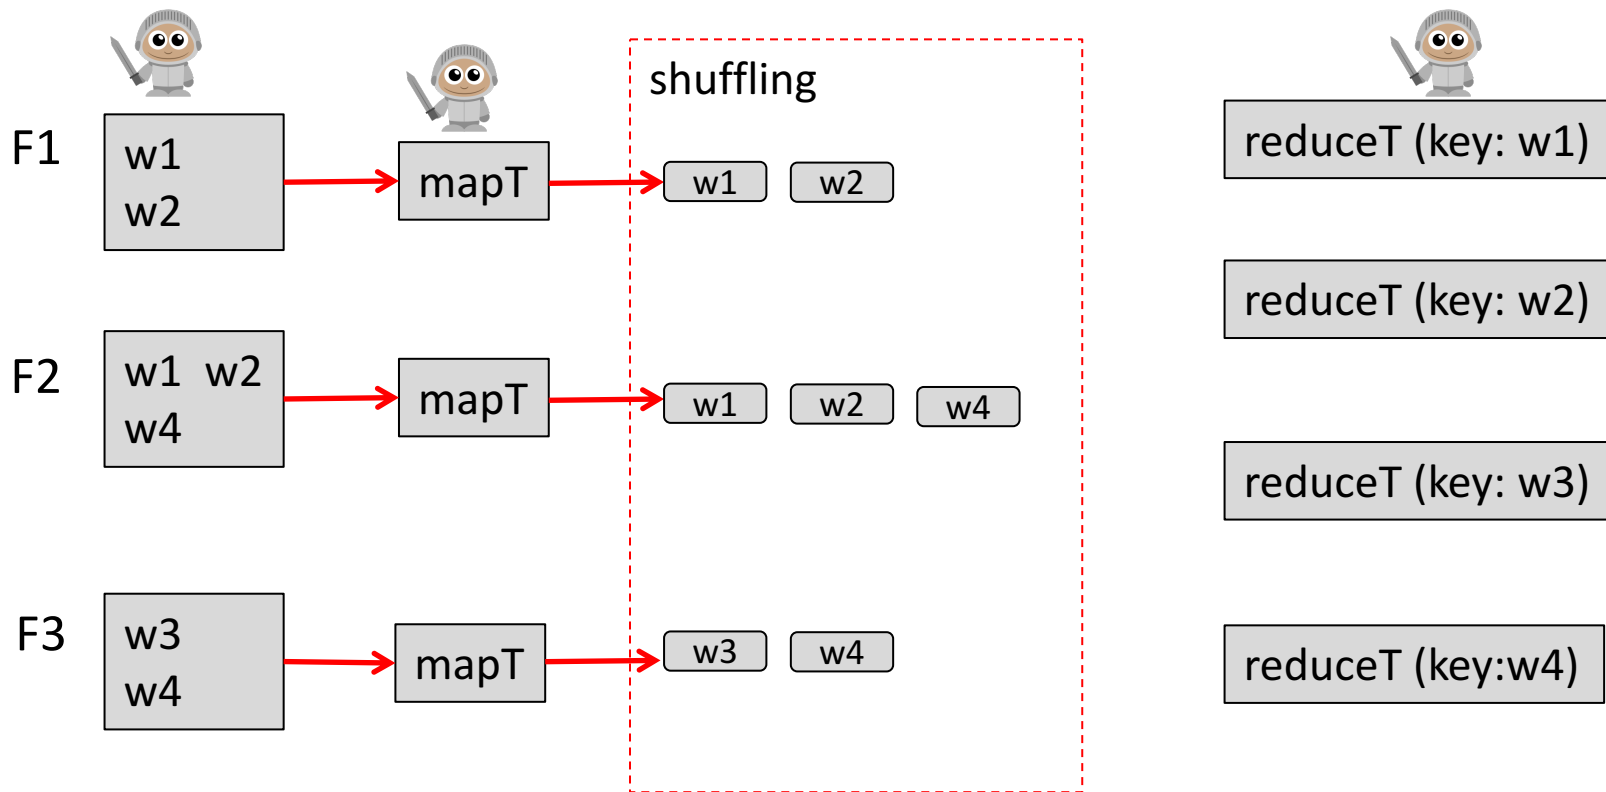

Identify small essential components of MapReduce to be included in the TCB.

# Challenge 2: Interactions Leaks Info

# Example of leakage: wordcount

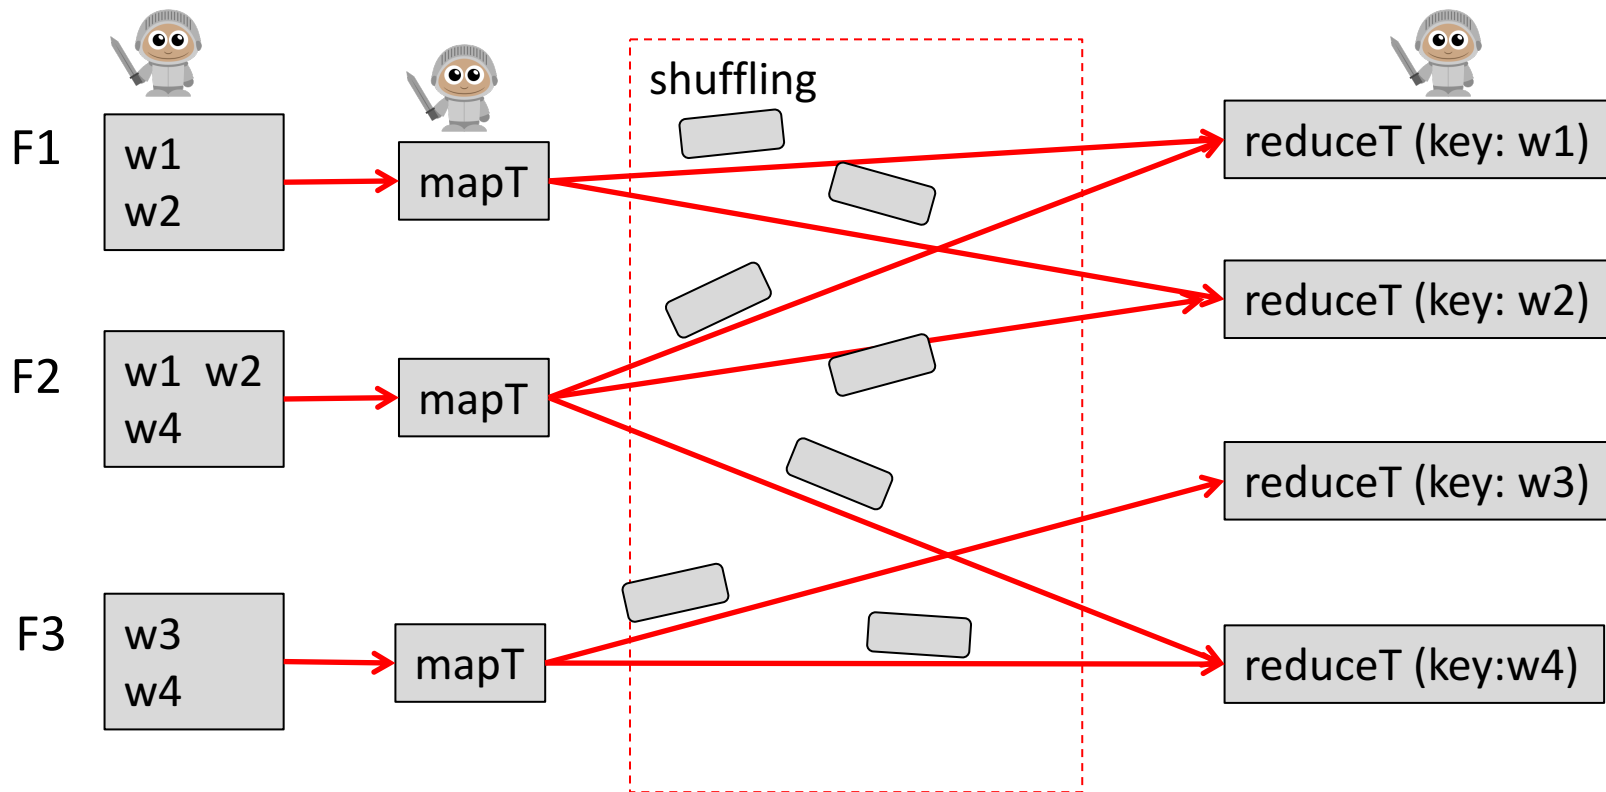

- Map Phase: each mapT generates the tuples.

# Example of leakage: wordcount

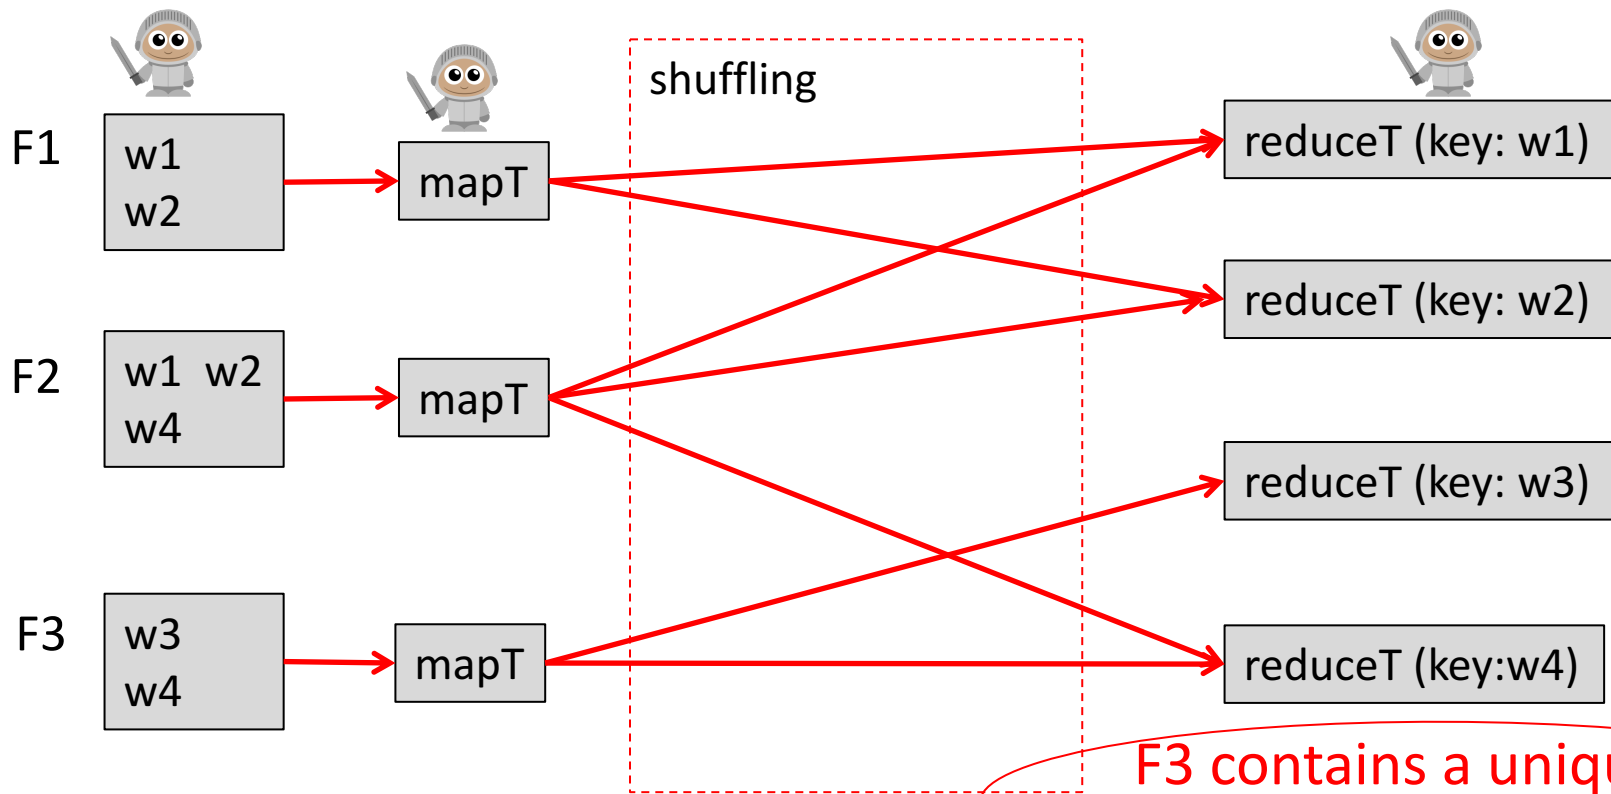

- Shuffling Phase: The tuples are grouped w.r.t the “words”.

- Reduce Phase: reduceT counts and outputs the number of tuples it received.

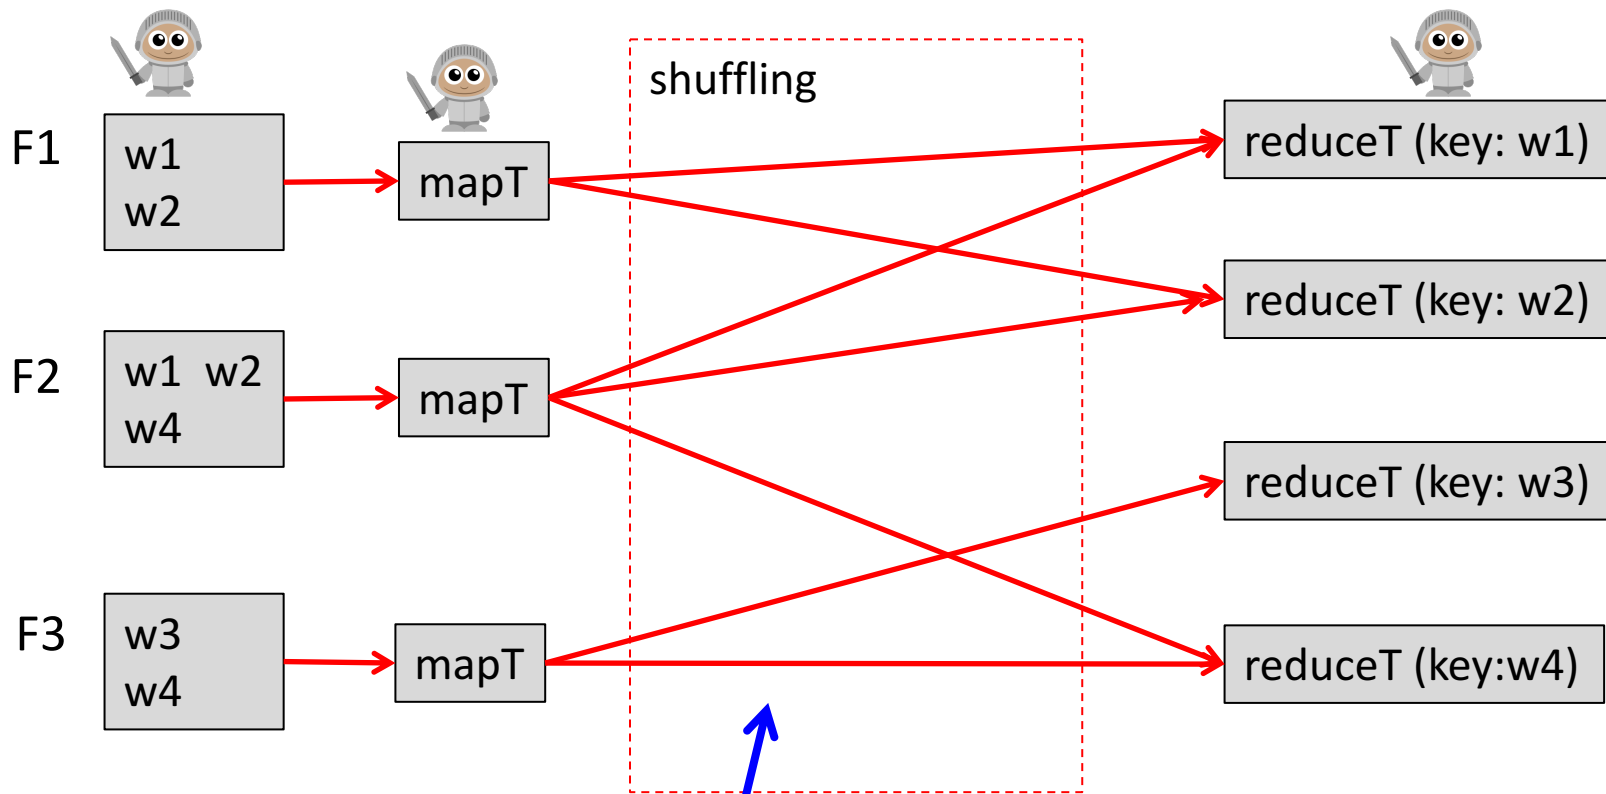

# Example of leakage: word counts

- By observing the flow of tuples, one can infer relationships among the input files.

# Example of leakage: word counts

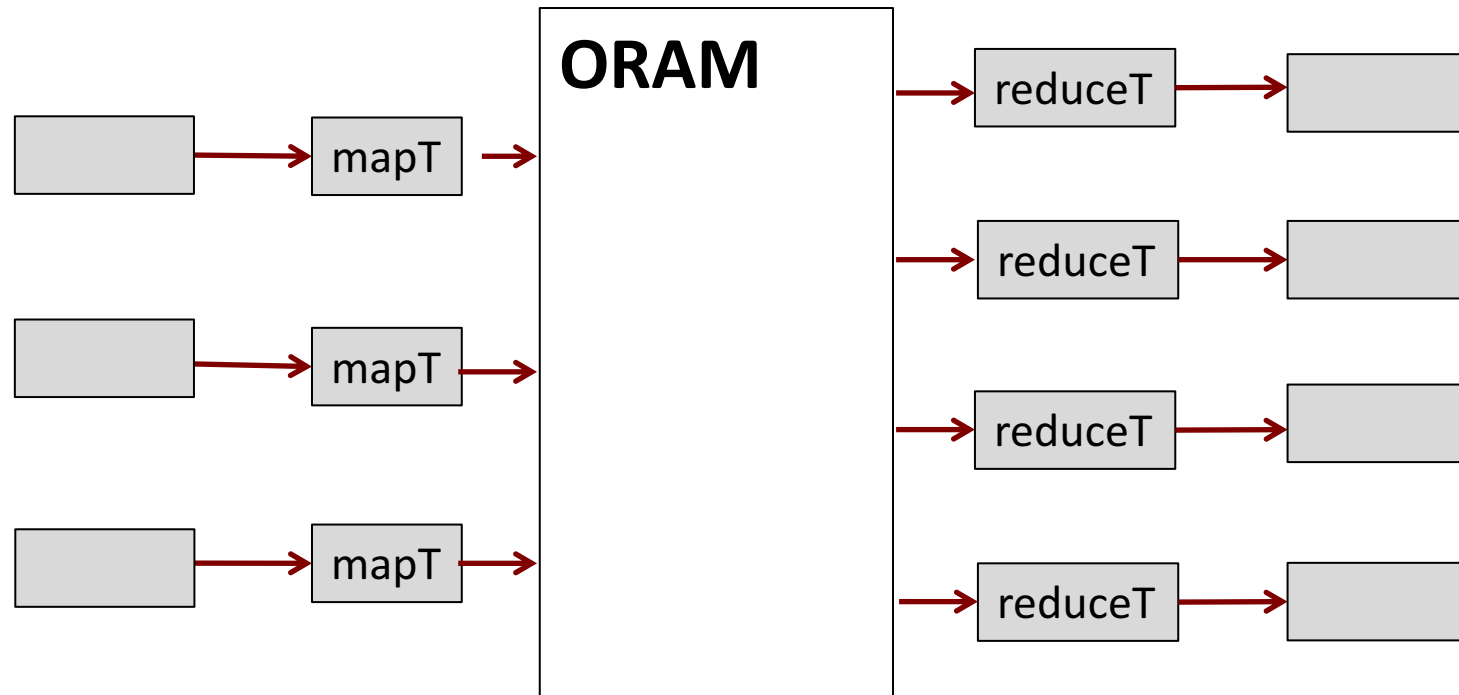

- By observing the flow of tuples, one can infer relationships among the input files.

**Goal: hide these relationships.**

# Possible solution: Oblivious RAM

- Very high overhead.

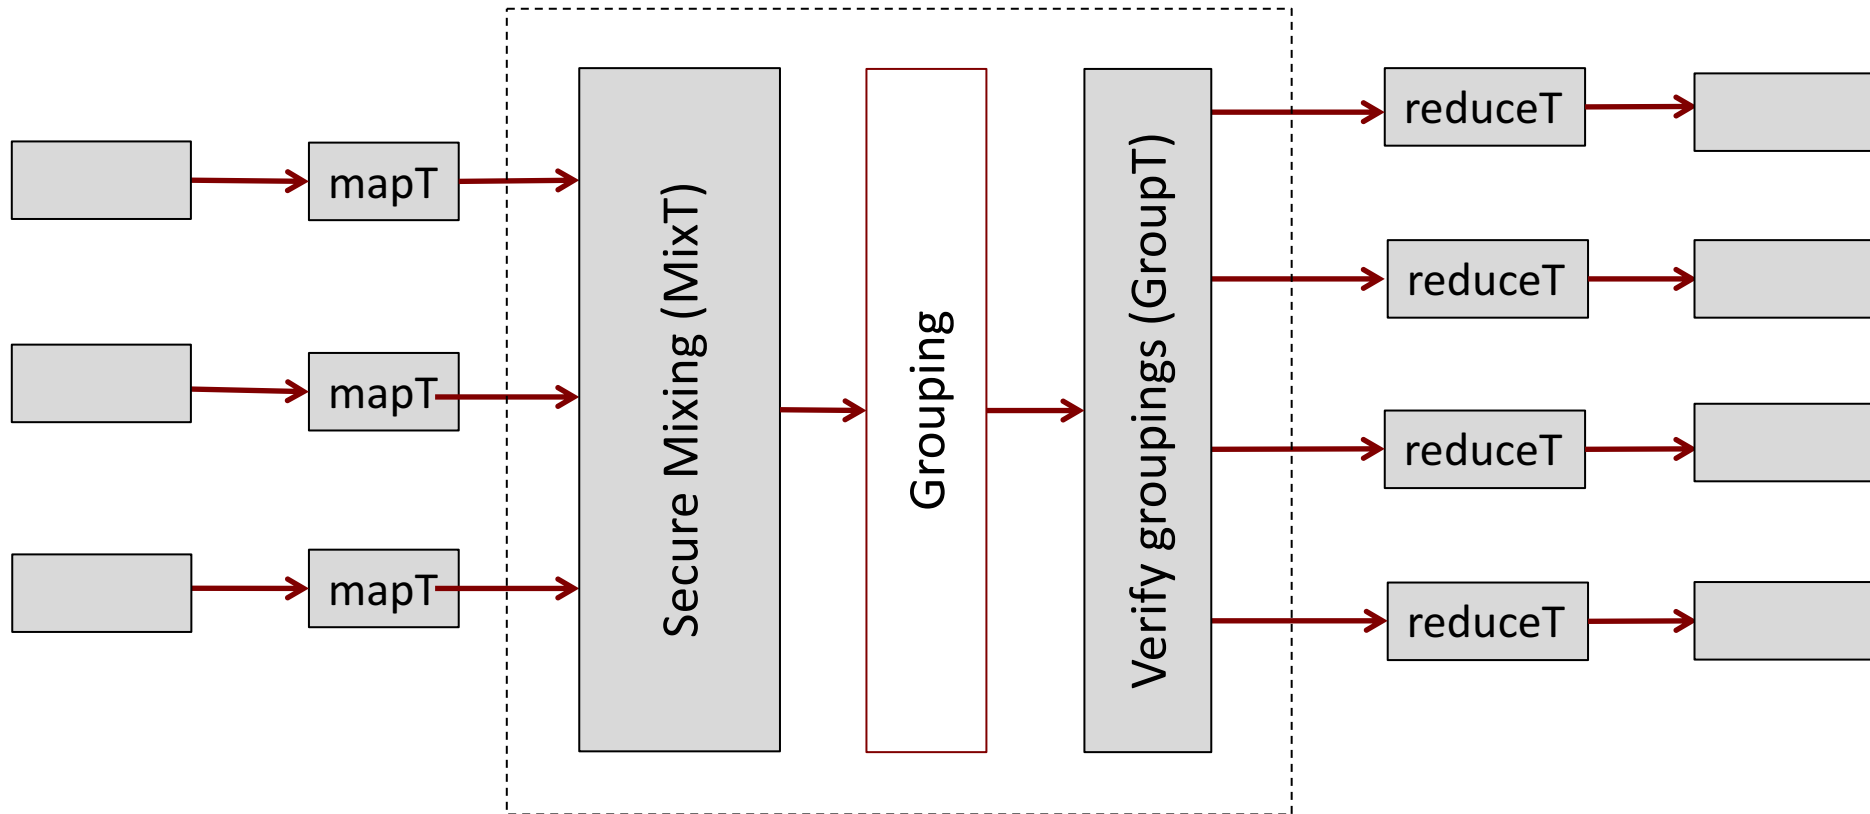

## 2. Our solution

- Randomly permutes the tuples.
- Group the tuples according to their keys.

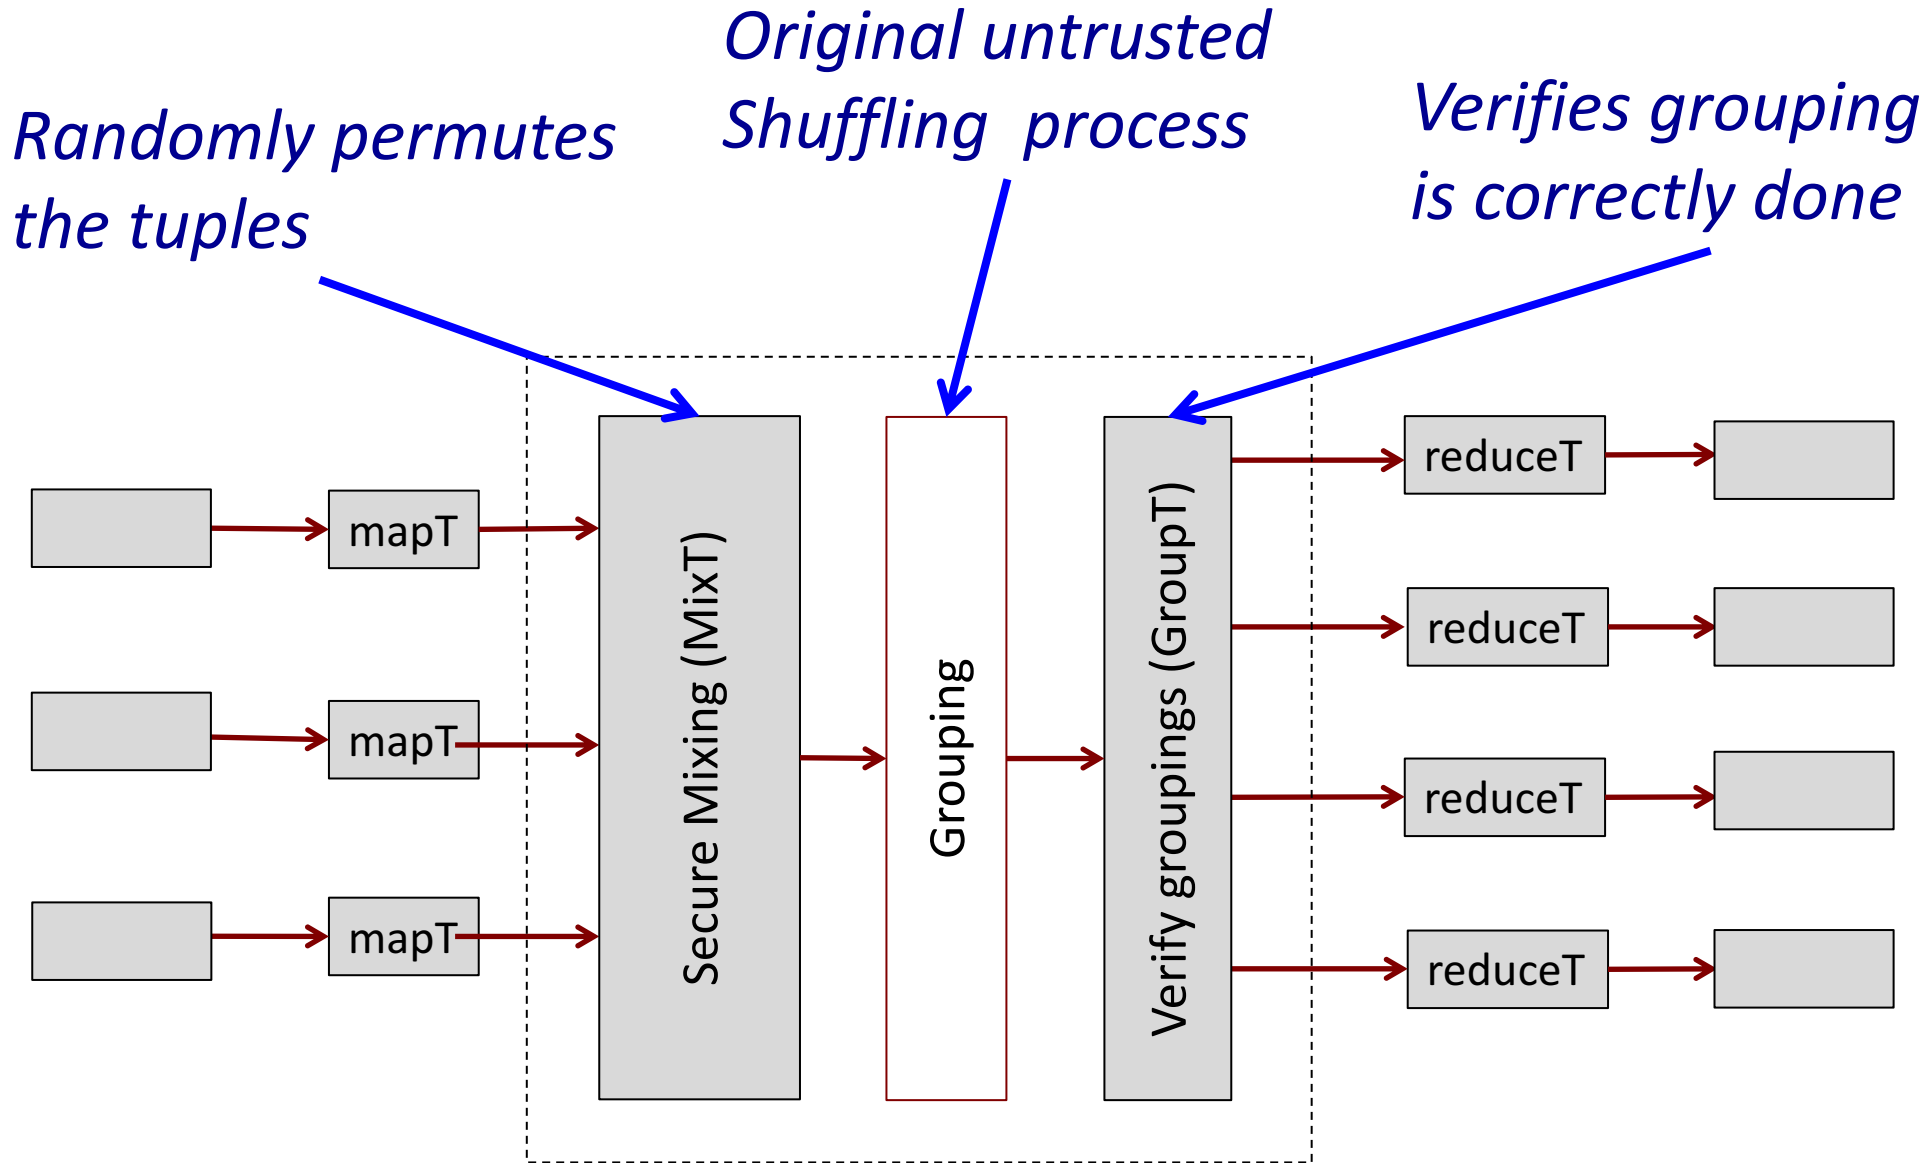

## 2. Our solution

- For execution integrity, addition step of verification is required.

## 2. Our solution

# Cascaded Mixing

A *cascaded mixing* is employed to randomly permute the tuples distributedly.

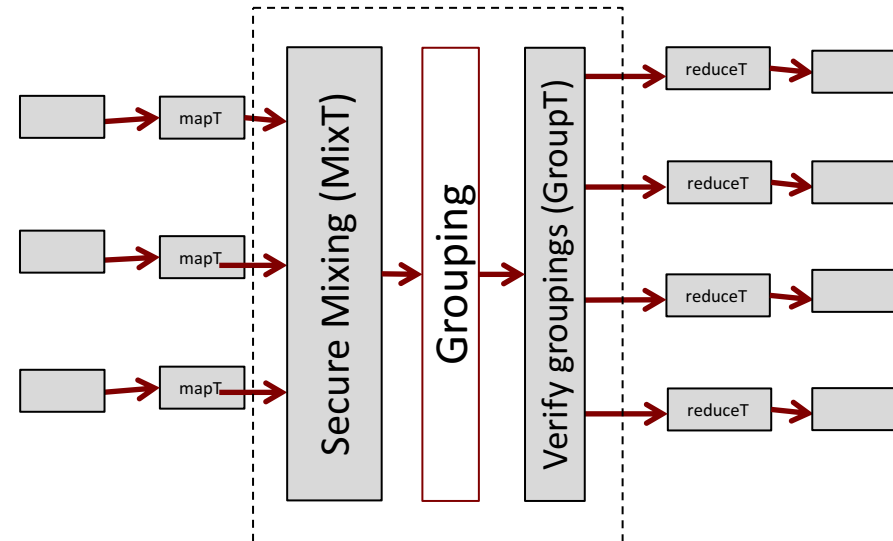

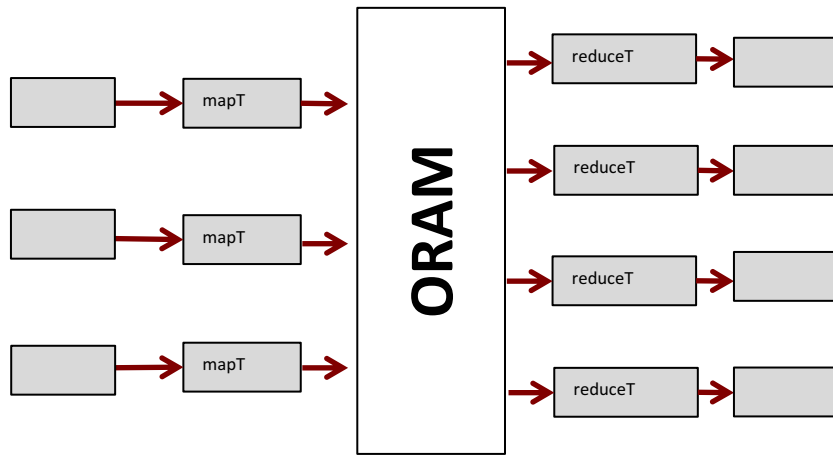

# Remarks

- Key management, handling of the random nonce and initial value is not straightforward.
- In Hadoop, multiple reduce instances are carried out by a single *reducer*. Likewise *mapper*.

# ORAM vs Our solution

- M<sup>2</sup>R exploits the fact that, reads and writes can be “batched” into 2 phases, whereas ORAM caters for single read/write and thus incurs higher overhead.
- Many constructions of ORAM need to permute or o-sort the data.

# 3. Security Model

Adversary can observe the following:

- Input/output size of each trusted instance.
- Source/destination of the input/output.
- Time of invocation/return of each trusted instance.

Active adversary can:

- Arbitrary Invoke trusted instances.
- Halt instances.
- Drop/duplicate ciphertext (encrypted tuples).
- Add delays.

# Modulo- $\Psi$ private

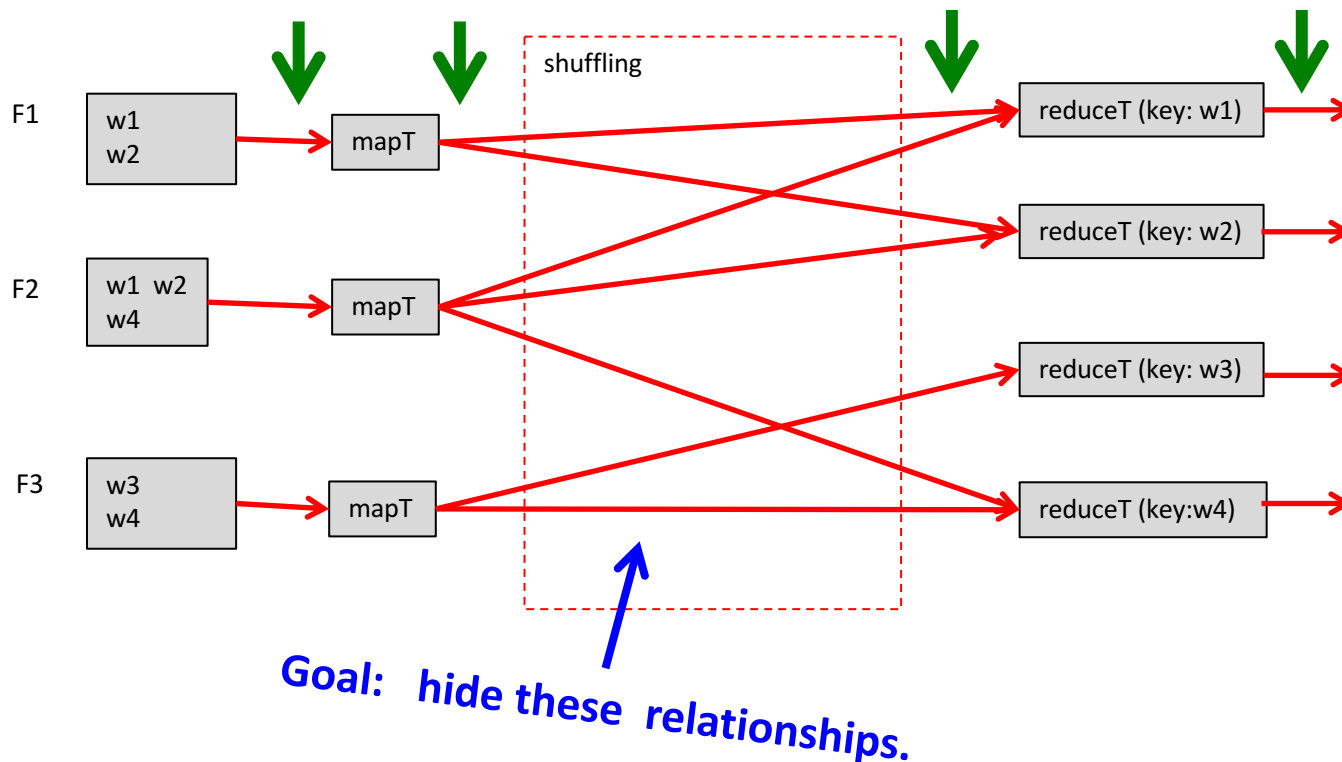

Based on formulation by Canetti (FOCS 01).

Let  $\Psi$  be the permissible data that can be revealed during honest execution.

*A provisioning protocol is modulo- $\Psi$  private if, for any adversary  $\mathcal{A}$  executing the protocol, there is an algorithm  $\mathcal{B}$  with access only to  $\Psi$ , such that the output of  $\mathcal{A}$  and  $\mathcal{B}$  are indistinguishable.*

The permissible  $\Psi$  :

- size of input/output, time of revocation/return of mapT and reduceT under honest execution.

*$M^2R$  is  $\Psi$ -modulo private.*

# 4. Implementations & Experiments

- Use Xen-4.3.3 as the trusted hypervisor, and its Verifiable Dynamic Function Executor to load and execute trusted codes. (The design of M<sup>2</sup>R can be implemented differently depending on the underlying architecture, e.g. on Intel SGX).
- Ported 7 MapReduce benchmark applications.
  - KMeans : Iterative, Compute intensive
  - Grep : Compute intensive
  - Pagerank : Iterative, Compute intensive
  - WordCount : Shuffle intensive
  - Index : Shuffle intensive
  - Join : database queries
  - Aggregate : database queries
- 8 compute nodes, each quad-core Intel CPU 1.8 GHz, 8GB RAM, 1GB Ethernet cards.

# Trusted Code Base

4 trusted computation units:  
mixT, GroupT, mapT, reduceT.

- Platform related: (mixT, GroupT)  
    Lines Of Code:  $\approx 300$
- Applications: (mapT, ReduceT)  
    Lines Of Code  $\approx 200$  for our examples.

# Performance

Job	Input size (bytes) (vs plaintext size)	Shuffled bytes	#Applications hyper calls	#platform hyper calls
Wordcount	2.1G (1.1×)	4.2G	$3.3 \times 10^6$	35
Index	2.5G (1.2×)	8G	$3.3 \times 10^6$	59
Grep	2.1G (1.1×)	75M	$3.3 \times 10^6$	10
Aggregate	2.0G (1.2×)	289M	$18.0 \times 10^6$	12
Join	2.0G (1.2×)	450M	$11.0 \times 10^6$	14
Pagerank	2.5G (4.0×)	2.6G	$1.7 \times 10^6$	21
KMeans	1.0G (1.1×)	11K	$12.0 \times 10^6$	8

# Running time (s)

Job	Baseline (vs no encryption)	M <sup>2</sup> R (vs baseline)
Wordcount	570 (2.6 ×)	1156 (2.0 ×)
Index	666 (1.6 ×)	1549 (2.3 ×)
Grep	70 (1.5 ×)	106 (1.5 ×)
Aggregate	125 (1.6 ×)	205 (1.6 ×)
Join	422 (2 ×)	510 (1.2 ×)
Pagerank	521 (1.6 ×)	755 (1.4 ×)
KMeans	123 (1.7 ×)	145 (1.2 ×)

# Conclusions

- Privacy-preserving distributed computation of MapReduce with trusted computing.
- Security:
  - Execution integrity +Data Confidentiality
  - Observation that simply running the map/reduce in trusted environment is not sufficient: interactions leak sensitive info.
  - Small TCB
- Exploit the algorithmic structure to outperform a solution that employs generic ORAM.
- Future works: other distributed dataflow systems.
