<ロ> <昂> < 臣> < 臣

From regions to zones Matrix notation and zone operations Closed zones and graph representation

## What is wrong with regions?

#### Unwieldy:

• The number of regions can be very large:

- It is exponential in the number of clocks, and in the size of the maximal constraints appearing in the clock constraints.
- As a result, practical verification of transition systems based on regional transition systems becomes infeasible.

イロト イヨト イヨト イヨト

# What is a zone?

From regions to zones Matrix notation and zone operations Closed zones and graph representation

#### A more compact representation:

...of equivalence classes of valuations....

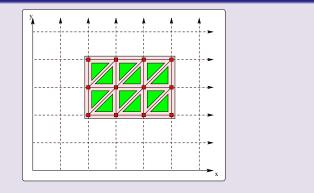

- Can be efficiently represented as Difference Bounded Matrices (edge weighted directed graphs).
- DBMs admit a canonical representation.
- DBMs can be manipulated efficiently.

From regions to zones Matrix notation and zone operations Closed zones and graph representation

#### Regions versus zones

#### 47 regions versus 1 zone!

#### 47 regions in zone $(2 \le x \le 5) \land (2 \le y \le 4)$

(日) (四) (三) (三)

Formally:

From regions to zones Matrix notation and zone operations Closed zones and graph representation

#### Definition of zone:

 A zone Z is a clock constraint of the "two-variable difference" form

$$\mathcal{Z} ::= \mathbf{x} \operatorname{op} \mathbf{c} \mid \mathbf{x} - \mathbf{y} \operatorname{op} \mathbf{c} \mid \mathbf{z}_1 \wedge \mathbf{z}_2$$

where  $op \in \{<, \leq, >, \geq\}$ , and  $c \in \mathbb{N}$ .

< □ > < □ > < □ > < □ > < □ >

From regions to zones Matrix notation and zone operations Closed zones and graph representation

## Zone is a convex hull

#### What is this?

- A zone Z is a convex union (or *hull*) of all the regions  $\mathcal{R}$ :  $Z = \bigcup_i \mathcal{R}_i$ .
- To encode zones in a DBM, we

X

- construct a new clock variable  $x_0$  which will always have the value 0, and then encode all constraints as  $x_i x_j < m$  or  $x_i x_j \leq m$  where  $m \in \mathbb{Z}$ .
- For example the following terms on the left are translated to those on the right:

(ロ) (四) (日) (日) (日)

\*\*

US

From regions to zones Matrix notation and zone operations Closed zones and graph representation

### Finiteness and hence termination

#### Ignore constraints bigger than $C_x$ :

- To ensure termination:
  - Remove constraints of the form x < m, x ≤ m, x − y < m and x − y ≤ m if m > C<sub>x</sub>.
  - Replace x > m,  $x \ge m$  with  $x > C_x$  if  $m > C_x$ .
  - Replace y x > m,  $y x \ge m$  with  $y x > C_x$  and  $y x \ge C_x$  if  $m > C_x$ .

< □ > < □ > < □ > < □ > < □ >

## Matrix notation

From regions to zones Matrix notation and zone operations Closed zones and graph representation

#### Compact notation:

For n - 1 clock variables, we then write out an  $n \times n$  matrix M, with elements drawn from  $(\mathbb{Z} \times \{<, \le\}) \cup \infty$  according to the following rules:

- For constraints like  $x_i x_j < c$ , set  $M_{i,j} = (c, <)$
- For constraints like  $x_i x_j \le c$ , set  $M_{i,j} = (c, \le)$
- Otherwise set  $M_{i,j} = \infty$

(日)

Matrix notation

From regions to zones Matrix notation and zone operations Closed zones and graph representation

#### Consider this clock zone:

$$(0 \le x_1 < 1) \land (0 < x_2 < 3) \land (x_2 - x_1 \ge 1)$$

#### then the DBM is

$$\begin{array}{c|cccc} & x_0 & x_1 & x_2 \\ \hline x_0 & (0,\leq) & (0,\leq) & (0,<) \\ x_1 & (1,<) & (0,\leq) & (-1,\leq) \\ x_2 & (3,<) & \infty & (0,\leq) \end{array}$$

< □ > < □ > < □ > < □ > < □ >

### Constructing regional/zone transition systems

#### Practice versus mathematics:

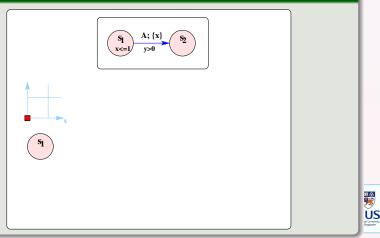

- In the mathematics, en-route to the finite RTS or ZTS, we construct (infinite) transition systems.
- This is fine, but not actually possible (obviously).
- Instead we generate the transition systems in one step from the TTS.
- The following slides attempt to show the flavour of the algorithm in pictures...

### **Operations on zones**

#### Zones are relatively easily manipulated:

- Following three operations are needed for use in evaluating zone transitions:
  - If D<sub>1</sub> and D<sub>2</sub> are two clock zones, then the intersection of the zones is a new clock zone D<sub>1</sub> ∧ D<sub>2</sub>.
  - D ↑ is the time-elapsed zone defined by
     D ↑= {V + δ | V ∈ D} with δ ∈ ℝ<sub>>0</sub>.
  - The clock-reset zone  $R_X \mathcal{D}$  is defined by  $R_X \mathcal{D} = \{R_X(V) \mid V \in \mathcal{D}\}$  where  $R_X(V)(\lambda) = 0$  if  $\lambda \in X$  or  $R_X(V)(\lambda) = V(\lambda)$  otherwise.

From regions to zones Matrix notation and zone operations Closed zones and graph representation

### Want a canonical representation

#### Equivalence of zones:

We do not want two different zones to represent the same set of valuations (i.e. (y − x ≤ 3, x = 2, y = 4) the same as (y − x = 2, x = 2, y = 4).

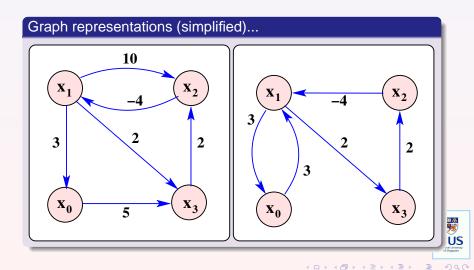

**Definition:** A zone is *closed* if no constraint can be strengthened without reducing the set of associated valuations.

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

From regions to zones Matrix notation and zone operations Closed zones and graph representation

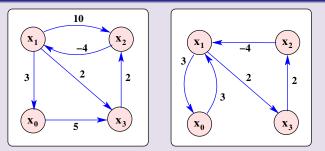

# Closed zones are equivalent iff identical

From regions to zones Matrix notation and zone operations Closed zones and graph representation

# Closed zones are equivalent iff identical

### Graph shortest path reduction:

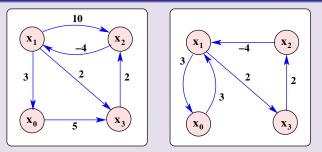

A shortest path reduction is performed on the graph (computed in  $O(n^3)$  time), where redundant edges are removed when they can be. For example  $x_1 \xrightarrow{10} x_2$  is replaced by  $x_1 \xrightarrow{2} x_3 \xrightarrow{2} x_2$ .

US al University Ingapore

From regions to zones Matrix notation and zone operations Closed zones and graph representation

# Closed zones are equivalent iff identical

### Graph shortest path reduction:

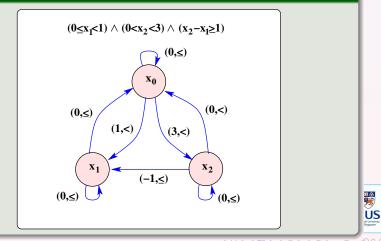

If *D* is closed then *D* is a subset of *D'* iff for every constraint  $x - y \le m'$  in *D'* there is  $x - y \le m$  in *D* with  $m \le m'$ . If *D* is closed then *D* is non-empty iff there are no negative weight cycles in the graph.

# **Behaviours**

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

### The behaviour of a TS...

- ...is its set of *runs*, or its set of *computations*.
- To verify behaviours against a property, we can consider questions like:
  - Does every computation (run) of the transition system have a desired property X ? or
  - Is it true that in no computation, C is immediately followed by on-ac?.

イロト イヨト イヨト イヨト

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

NUS

## Safety and Liveness

#### Two types of behaviours:

- In handouts, the ideas of safety and liveness were introduced, identifying two types of behaviours that require different analysis methods.
  - A safety property is like "something bad doesn't happen", whereas
  - liveness is like "something bad (or good) must eventually happen".
- We can often formulate safety properties in terms of the reachability of a state.

イロト イヨト イヨト イヨト

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

# Checking TS

#### What is an automata?

- An automata is a state transition system with some set of accepting states, which may be used to distinguish between good and bad computations.
- We can use automata matching a particular transition system to specify *desired* behaviour of the system, in a form like "Is there a run of the automaton that leads to the (desired) accepting state?", or "Is there a run of the automaton that leads to an accepting state in which property *P* holds?".
- These are examples of a reachability problem.

< D > < B > < E > < E</p>

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

### Finite automaton

### Definition:

A finite automaton is a 5-tuple  $(Q, \Sigma, \Delta, q_0, F)$ , where

- Q is a finite set called the states
- Σ is a finite set called the alphabet
- $\Delta : Q \times \Sigma \rightarrow Q$  is the transition function
- q<sub>0</sub> is the start state
- F 
  Q is the set of accepting states

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

# Checking TS

### Automata theory...

- These sort of problems have clear links to automata theory, and
- we could easily cast a lot of this discussion in terms of the languages accepted by (finite) automata.
- To reason about liveness properties, we need to consider infinite sequences.
- A Büchi automaton is an extension of a finite state automaton to one which accepts an infinite input sequence if, and only if, there is a run of the automaton which has infinitely many states in the set of final states.

(日) (四) (三) (三)

Büchi automata

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

### Definition:

A Büchi automaton is a 5-tuple  $(Q, \Sigma, \Delta, q_0, F)$ , as for a regular automaton, but with F interpreted differently. In particular  $s_0 a_0 s_1 a_1 s_2 \dots$  is an accepting infinite trace if

- $s_0 \in Q$
- $(s_i, a_i, s_{i+1}) \in \Delta$  for all *i*
- For infinitely many *j*, the state s<sub>j</sub> is in *F*

(日) (四) (三) (三)

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

## Büchi automata

#### What are they good for?

- They are useful for specifying behavior of nonterminating systems, such as
  - hardware (electronic circuits) or
  - operating systems.
- For example, you may want to specify a property like
  - "for every measurement, a recording eventually follows", or
  - the reverse "there is a measurement which is not followed by a recording".
- For the second example, an argument limited to finite sequences cannot satisfy this property.

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

## Properties: Reachability and deadlock

#### Are related...

- For example, is there a run leading to *deadlock*?
- A deadlocked system can do no more computation, more formally:

**Definition**: The run  $s_0 \stackrel{*}{\Longrightarrow} s_k$  with  $s_0 \in S_{in}$  is in **deadlock** if no action is enabled at  $s_k$ .

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

### Properties: qualitative

#### Questions such as...

- Every request is eventually served.
- The sensor signal x11 is sensed infinitely often.
- From any stage of the computation the all clear state can be reached within 3 steps

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

## Properties: quantitative

#### Questions such as...

- Every request is served within 3 microseconds.
- The sensor signal x11 is sensed every 10 milliseconds for ever.
- From any stage of the computation the all clear state can be reached within 1 second.

イロト イヨト イヨト イヨト

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

NUS

## The universe is not black and white

#### Consider...

Please answer YES or NO: Will the next answer you give me be NO?

You are either going to die in a bomb raid or you are not...

- *Extensional* logic means that you can determine the truth of a formula from the truth values of its parts.
- Intensional/modal logic refers to QUALIFIED truth (words like could, eventually, possibly and so on).

< D > < B > < E > < E</p>

Modal logic

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

### QUALIFIED truth

- The basic modal operators are
  - U which represents necessity and
  - its dual  $\Diamond$  which represents possibility ( $\Diamond A = \neg \Box \neg A$ ).

### The language of modal logic consists of

- propositional variables,
- a set of Boolean connectives such as  $\{\land, \lor, \neg\}$ , and
- the modal operators.

(日) (四) (三) (三)

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

# Temporal logic (a modal logic)

### Consider...

"The engine is too hot."

- The meaning is clear, it does not vary with time, but ...
- the truth value of the assertion *can* vary in time.
  - Sometimes it is true, and sometimes it is false, and
  - it is never true and false simultaneously.
- Temporal logics are a good mechanism for expressing *qualitative* temporal properties of reactive systems.
- Operators related to TIME, so that (for example) □φ means that propositional variable φ must hold in all the following (later) states.

ヘロア ヘロア ヘビア ヘビ

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

> **10 75**

US

## **Temporal operators**

#### Common to use mnemonic letters X,G,F,U,R...

- Operators:
  - $X \phi$  indicating that  $\phi$  must hold in the next state.
  - G φ (or □ φ) indicating that φ must hold in all the following states.
  - F φ (or ◊ φ) indicating that eventually (finally) φ must hold somewhere.
  - $\phi U \psi$  indicating that  $\phi$  has to hold until  $\psi$  holds at the current or a future position.
  - φ R ψ The dual of U, ψ holds until the first state where φ holds.

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

# LTL versus CTL

#### Linear Temporal Logic, Computation Tree Logic

- In LTL, one can encode formulæ about events along a single computation path.
- By contrast, CTL is a modal *branching-time* temporal logic. The operators quantify over all possible future paths from a given state.
- CTL and LTL are both subsets of a more general temporal logic CTL\*.
- There are expressions in CTL that cannot be expressed in LTL and vice versa.
- In CTL formulæ each of the temporal operators must be preceded by a *path* quantifier: A, or E.

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

# LTL≠CTL

### Consider this TS:

- A(FG *p*), is an LTL formula representing: for all paths, eventually *p* holds globally (i.e. from then on).
- AF(AG p) is CTL for: for all paths, eventually you get to a state where for all paths p holds globally (i.e. from then on).
- LTL formula is not the same thing as CTL formula.

LTL≠C<u>TL</u>

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

3

ŬS

### LTL: All runs that start in *s* have *p* holding eventually:

The possible (infinite) runs from s are

or...

 $\left.\begin{array}{c} sssssssss \dots \end{array}\right\} \quad i.e. \ s^{\infty}$   $\left.\begin{array}{c} stuuuuuu \dots \\ sstuuuuu \dots \\ ssstuuuu \dots \\ \dots \end{array}\right\} \quad i.e. \ ss^{*}tu^{\infty}$ 

so in the linear time view, for state s, A(FG p).

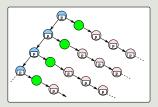

LTL≠CTL

Behaviour, safety, liveness, automata, reachability... Extensional and intensional logic Linear and branching time

### CTL: Eventually you get to where *p* holds from then on:

### The CTL counterexample for AF(AG p) is

so in the CTL view, for state s, AF(AG p) is not true.
