CS3243 Foundations of Artificial Intelligence

(Textbook section 25.1, 25.2, 25.3, 25.4, 25.6)

Slides due to Huang Weihua

Outline

A decorative graphic at the top of the slide consists of two groups of circles. The first group on the left has a solid light purple circle behind the word 'Outline' and an empty light purple circle outline to its right. The second group on the right has a solid light purple circle, an empty light purple circle outline, and another solid light purple circle.

 - Localization
- Motion Planning
- Move

Definition

- A robot is a physical agent equipped with sensors and effectors that can perform certain task in the physical world.
- Categories:
 - Manipulator: robot arms.
 - Mobile: environment navigation.
 - Hybrid: mobile + manipulator, e.g. humanoid robot.

Definition

- Example:

Hardware

A decorative graphic consisting of six circles arranged in two rows. The top row has three circles: a solid light purple circle, an outlined light purple circle, and a solid light purple circle. The bottom row has three circles: a solid light purple circle, an outlined light purple circle, and a solid light purple circle.

- Sensors: perceptual interface between the robot and the environment.
- Passive sensor: capture signals generated by other sources in the environment, e.g. a touch sensor.
- Active sensor: send energy into the environment and capture the reflected energy.

Hardware

A decorative graphic consisting of two rows of circles. The top row has a solid light purple circle on the left and an outlined light purple circle on the right. The bottom row has a solid light purple circle on the left, an outlined light purple circle in the middle, and a solid light purple circle on the right.

- Sensor types

- Range finder: measure distance to other objects in the environment, e. g. light sensor, sonar, GPS.
- Imaging sensor: provides models and features in the environment, using computer vision techniques, e.g. camera.
- Proprioceptive sensors: detects the state of the robot itself, e.g. rotational sensor.

Hardware

- Effectors: enables a robot to move and perform actions.
- Example:

Hardware

A decorative graphic consisting of six circles arranged in two rows. The top row has two circles: a solid light purple one on the left and an outlined light purple one on the right. The bottom row has three circles: a solid light purple one on the left, an outlined light purple one in the middle, and a solid light purple one on the right.

- Degree of freedom (DOF): independent direction in which one of the effectors can move.
- Example: an AUV has six degrees of freedom: (x, y, z) and three angular orientation.
- Kinematic state: set of all the degrees of freedom.

Hardware

- Effective DOF vs. Controllable DOF:

- A robot is nonholonomic if:

$\# \text{ of effective DOF} > \# \text{ of controllable DOF}$

- A robot is holonomic if:

$\# \text{ of effective DOF} > \text{controllable DOF.}$

Hardware

- Wheels vs. legs

- Wheel-based designs are easier to implement (differential drive or synchro drive).

- Legs can handle more rough terrain, but are mechanically difficult to build. (Dynamic stability and static stability)

Hardware

- Electric motor

- Most popular mechanism to provides power to drive the effectors.
- Actuation the manipulator and controls locomotion.

Robotic Perception

- Perception is the process of mapping sensor measurements into internal representations of the environment.
- Difficulties: environment is partially observable, unpredictable and dynamic.

Robotic Perception

- Bayes Network representation

Where A_i are the actions, X_i are the states and Z_i are the observations.

Robotic Perception

- Localization: determine the location of things in the environment.
 - Tracking: the initial location of an object is known.
 - Global localization: finding a target whose initial location is unknown.
 - Kidnapping problem: the target object is “kidnapped” to test the robustness of the robot.

Motion Planning

- **Workspace:** coordinates characterize the full state of the robot. (x, y, z, \dots)
- **Configuration space:** coordinates characterize the configuration of the robot's joints. (rotational angles etc.)
- **Free space:** all configurations that the robot is allowed to reach.

Motion Planning

- Cell-decomposition methods: divide the free space into a finite number of contiguous regions (cells).
 - Path planning => graph search.

Motion Planning

- Simplest cell decomposition: cell = regular grid.
- Problem: too expensive for high-dimensional configuration space. Mixed cells make the method unsound and incomplete.
- Solution: subdivision and irregular cells.

Motion Planning

A decorative graphic consisting of six circles arranged in two rows of three. The top row has a solid light purple circle on the left, a hollow light purple circle in the middle, and a solid light purple circle on the right. The bottom row has a solid light purple circle on the left, a hollow light purple circle in the middle, and a solid light purple circle on the right.

- Potential field: a function defined over the state space, whose value grows with the distance to the closest obstacle.
- Minimize the path lengths and stay away from the obstacles by following the smallest values.
- Problem: local minimum

Motion Planning

Motion Planning

A decorative graphic consisting of six circles arranged in two rows. The top row has three circles: a solid light purple circle, a hollow light purple circle, and a solid light purple circle. The bottom row has three circles: a solid light purple circle, a hollow light purple circle, and a solid light purple circle.

- Skeletonization methods: reduce the free space to a one-dimensional representation.
- Voronoi graph: contains points that are equidistant to neighboring obstacles.
- Probabilistic roadmap: randomly generate candidates in the free space and link them.

Motion Planning

- Example:

Move

- Dynamic state: extends the kinematic state of a robot by modeling the velocities, which is more complex.
- In real-life, a simple kinematic path planner is used together with a controller to keep the robot on track.

Move

- Reference controller: keep the robot on a preplanned path.
- Optimal controller: optimize a global cost function, such as the potential field function.
- Reactive controller: reflex design that makes decision based on feedbacks.

Move
