Bioinformatics and Biomarker Discovery Part 1: Foundations

Limsoon Wong 28 August 2008

Themes of Bioinformatics

Bioinformatics =

Data Mgmt +

Knowledge Discovery +

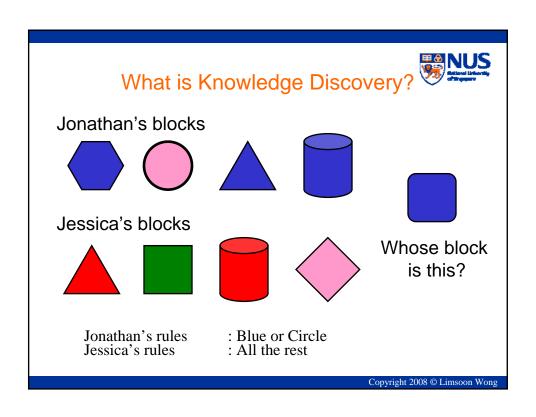

Sequence Analysis +

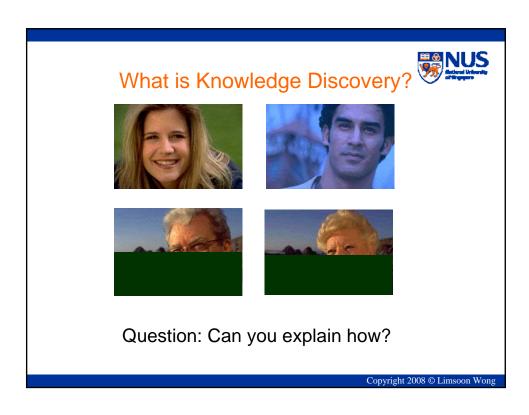

Physical Modeling +

Knowledge Discovery =

Statistics + Algorithms + Databases

Applications include diagnosis, prognosis, & treatment optimization, often thru biomarker discovery

- Training data gathering
- Feature generation
 - k-grams, colour, texture, domain know-how, ...
- Feature selection
 - Entropy, χ2, CFS, t-test, domain know-how...
- Feature integration
 - SVM, ANN, PCL, CART, C4.5, kNN, ...

What is Accuracy?

What is Accuracy?

	predicted	predicted
	as positive	as negative
positive	TP	FN
negative	FP	TN

Accuracy =
$$\frac{\text{No. of correct predictions}}{\text{No. of predictions}}$$

$$= \frac{\text{TP + TN}}{\text{TP + TN + FP + FN}}$$

Examples (Balanced Population)

classifier	TP	TN	FP	FN	Accuracy
Α	25	25	25	25	50%
В	50	25	25	0	75%
С	25	50	0	25	75%
D	37	37	13	13	74%

- Clearly, B, C, D are all better than A
- Is B better than C, D?
- Is C better than B, D?
- Is D better than B, C?

Accuracy may not tell the whole story

classifier	TP	TN	FP	FN	Accuracy
Α	25	75	75	25	50%
В	0	150	0	50	75%
С	50	0	150	0	25%
D	30	100	50	20	65%

- Clearly, D is better than A
- Is B better than A, C, D?

Exercise: What is B's Prediction strategy?

What is Sensitivity (aka Recall)?

	predicted	predicted
	as positive	as negative
positive	TP	FN
negative	FP	TN

No. of correct positive predictions

Sensitivity = _ No. of positives wrt positives

$$=\frac{TP}{TP + FN}$$

Sometimes sensitivity wrt negatives is termed specificity

What is Precision?

	predicted	predicted
	as positive	as negative
positive	TP	FN
negative	FP	TN

$$\frac{\text{Precision}}{\text{wrt positives}} = \frac{\text{No. of correct positive predictions}}{\text{No. of positives predictions}}$$

$$= \frac{\text{TP}}{\text{TP} + \text{FP}}$$

Copyright 2008 © Limsoon Wong

classifier	TP	TN	FP	FN	Accuracy	Sensitivity	Precision
Α	25	75	75	25	50%	50%	25%
В	0	150	0	50	75%	0%	ND
С	50	0	150	0	25%	100%	25%
D	30	100	50	20	65%	60%	38%

- What are the sensitivity and precision of B and C?
- Is B better than A, C, D?

Abstract Model of a Classifier

- Given a test sample S
- Compute scores p(S), n(S)
- Predict S as negative if p(S) < t * n(s)
- Predict S as positive if $p(S) \ge t * n(s)$

t is the decision threshold of the classifier

changing *t* affects the recall and precision, and hence accuracy, of the classifier

Copyright 2008 © Limsoon Wong

An Example

ន	P(S)	N(S)	Actual	Predicted	Predicted
			Class	Class	Class
				0 t = 3	0 t = 2
2	0.961252	0.038748	P	P N	P N
3	0.435302	0.564698	И	N	N
6	0.691596	0.308404	P	N	P
7	0.180885	0.819115	N	N	N
8	0.814909	0.185091	P	P	P
10	0.887220	0.112780	P	P	P
			accuracy	3 / 6 4/6	6/6 5/6
			recall	3 / 4 2/4	4/4 3/4
			precision	3/3 2/2	4/4 3/3

Recall that ...

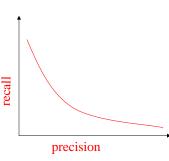

- Predict S as negative if p(S) < t * n(s)
- Predict S as positive if $p(S) \ge t * n(s)$

Exercise: Find the mistake in this table

Precision-Recall Trade-off

- A predicts better than B if A has better recall and precision than B
- There is a trade-off between recall and precision

- In some applications, once you reach a satisfactory precision, you optimize for recall
- In some applications, once you reach a satisfactory recall, you optimize for precision

Comparing Prediction Performance

- Accuracy is the obvious measure
 - But it conveys the right intuition only when the positive and negative populations are roughly equal in size
- Recall and precision together form a better measure
 - But what do you do when A has better recall than
 B and B has better precision than A?

So let us look at some alternate measures

Adjusted Accuracy

• Weigh by the importance of the classes

Adjusted accuracy =
$$\alpha$$
 * Sensitivity + β * Specificity where $\alpha + \beta = 1$ typically, $\alpha = \beta = 0.5$

classifier	TP	TN	FP	FN	Accuracy	Adj Accuracy
Α	25	75	75	25	50%	50%
В	0	150	0	50	75%	50%
С	50	0	150	0	25%	50%
D	30	100	50	20	65%	63%

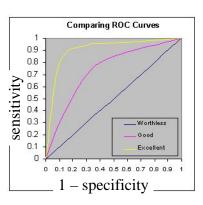

But people can't always agree on values for α , β

ROC Curves

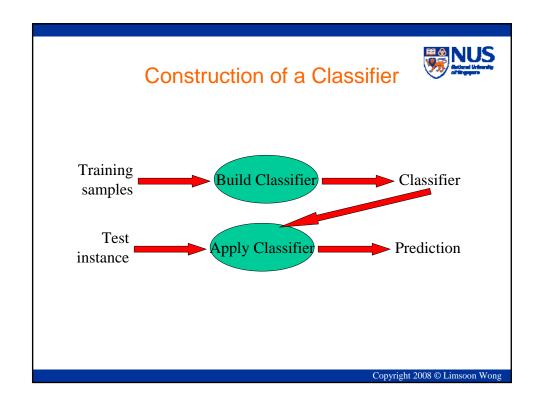

NUS

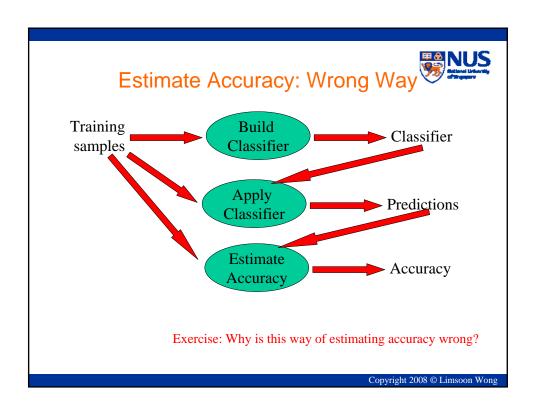

- By changing t, we get a range of sensitivities and specificities of a classifier
- A predicts better than B if A has better sensitivities than B at most specificities
- Leads to ROC curve that plots sensitivity vs. (1 – specificity)
- Then the larger the area under the ROC curve, the better

What is Cross Validation?

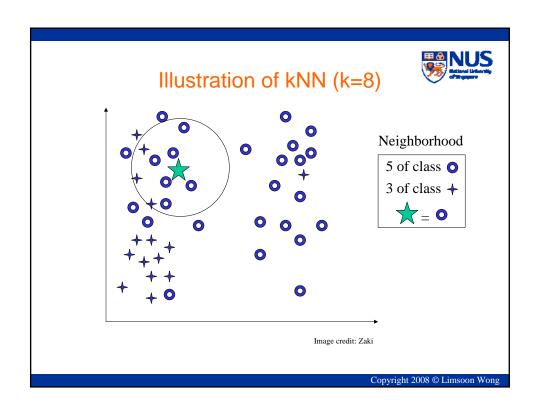

K-Nearest Neighbour Classifier (k-NA)

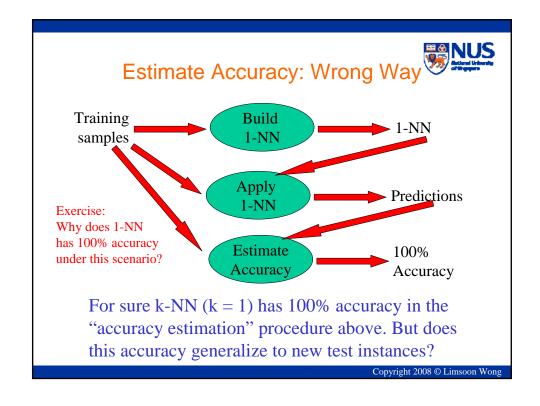

- Assume S is well approximated by its neighbours
- Then, given a sample S, find the k observations $S_1 \dots S_k$ in the known data that are "closest" to it, and average their responses

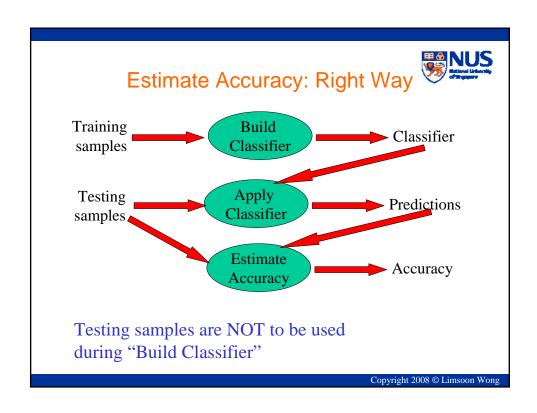

$$p(S) = \sum_{S_i \in N_k(S) \cap D^p} 1 \qquad n(S) = \sum_{S_i \in N_k(S) \cap D^N} 1$$

where $N_k(S)$ is the neighbourhood of S defined by the k nearest samples to it.

Assume distance between samples is Euclidean distance for now

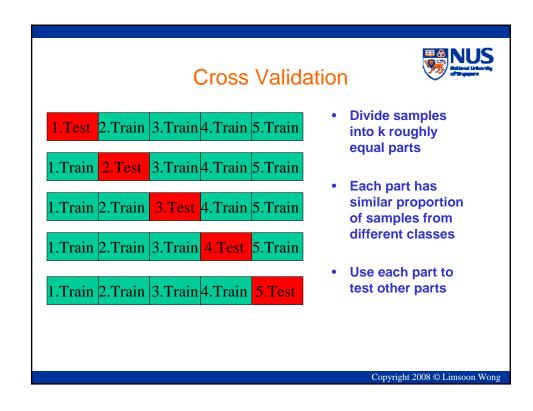

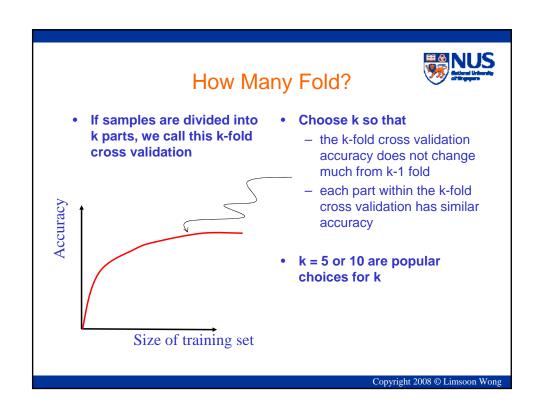

How Many Training and Testing Samples?

- No fixed ratio between training and testing samples; but typically 2:1 ratio
- Proportion of instances of different classes in testing samples should be similar to proportion in training samples
- What if there are insufficient samples to reserve 1/3 for testing?
- Ans: Cross validation

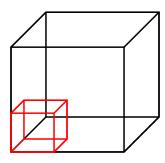

Curse of Dimensionality

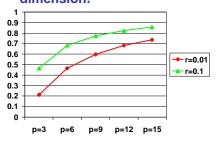

Curse of Dimensionality

 How much of each dimension is needed to cover a proportion r of total sample space?

- Calculate by $e_p(r) = r^{1/p}$
- So, to cover 10% of a 15-D space, need to sample (0.1)^{1/15} = 85% of each dimension!

Exercise: Why $e_p(r) = r^{1/p}$?

Consequence of the Curse

- Suppose the number of samples given to us in the total sample space is fixed
- Let the dimension increase
- Then the distance of the k nearest neighbours of any point increases
- Then the k nearest neighbours are less and less useful for prediction, and can confuse the k-NN classifier (and other types of classifiers as well)

What is Feature Selection?

Tackling the Curse

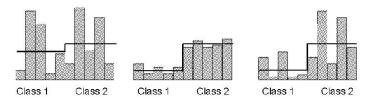

- Given a sample space of p dimensions
- It is possible that some dimensions are irrelevant
- Need to find ways to separate those dimensions (aka features) that are relevant (aka signals) from those that are irrelevant (aka noise)

Copyright 2008 © Limsoon Wong

Signal Selection (Basic Idea)

- Choose a feature w/ low intra-class distance
- Choose a feature w/ high inter-class distance

Signal Selection (e.g., t-statistics)

The t-state of a signal is defined as

$$t = \frac{|\mu_1 - \mu_2|}{\sqrt{(\sigma_1^2/n_1) + (\sigma_2^2/n_2)}}$$

where σ_i^2 is the variance of that signal in class i, μ_i is the mean of that signal in class i, and n_i is the size of class i.

Self-fulfilling Oracle

- Construct artificial dataset with 100 samples, each with 100,000 randomly generated features and randomly assigned class labels
- Select 20 features with the best t-statistics (or other methods)
- Evaluate accuracy by cross validation using only the 20 selected features
- The resultant estimated accuracy can be ~90%
- But the true accuracy should be 50%, as the data were derived randomly

What Went Wrong?

- The 20 features were selected from the whole dataset
- Information in the held-out testing samples has thus been "leaked" to the training process
- The correct way is to re-select the 20 features at each fold; better still, use a totally new set of samples for testing

Concluding Remarks

What have we learned?

- Methodology of data mining
 - Feature generation, feature selection, feature integration
- Evaluation of classifiers
 - Accuracy, sensitivity, precision
 - Cross validation
- Curse of dimensionality
 - Feature selection concept
 - Self-fulfilling oracle
